JOHNS HOPKINS HOSPITAL MAY 1. 1900. LIBRARY.

INDEX TO VOLUME CXVII.

Abbe, R. General consideration of the surgical treatment of empyema, 15.

Abdominal Surgery. The surgery of the abdomen, illustrated by eight cases, Cheever, D. W., 6, 12; laparotomy for pus in the abdominal cavity and for peritonitis, Irish, J. C., 145; a series of intra-abdominal operations, Richardson, M. H., 225, 230; gun-shot wounds of the abdomen, Parkes, C. T., 239; an experimental contribution to intestinal surgery, with especial reference to the treatment of intestinal obstruction, Senn, N., 239; three hundred and eighty-four laparotomies for various diseases, Homans, J., 263; an important point connected with abdominal surgery, Hewson, A., 264; when is colotomy justifiable, Mathews, J. M., 264; discussion of papers on abdominal surgery, 265; three cases of laparo-nephrotomy, Maclain, D., 266; gun-shot wounds of the abdomen, Manley, T. H., 310; a stab-wound of the abdomen, Formad, H. F., 337; abdominal tumors, Homans, J., 361; symptoms indicating injury of the abdominal organs: recovery under medical treatment, Packard, J. H., 445; laparotomy for tubercular peritonitis, 517.

Abdominal Supporter. A new form of abdominal supporter, Debaker, F., 263.

Abscess. Report of some cases of liver-abscess and their treatment, Grant, 286; the treatment of psoas abscess by posterior lumbar incision, Sayre, L. H., 286.

Actinomycosis. Actinomycosis in a woman, Hoeffner, 565.

Addison's Disease. Cases of Addison's disease, Davidson, 542.

Advertising. Advertising champagne, 639.

Agoraphobia. A case of agoraphobia, Biodgett, A. N., 407, 409.

Albuminuria. Albuminuria in health, Stewart, G., 94; separation of the retina in both eyes with albuminuria of pregnancy, Wadsworth, O. F., 184; pathology of albuminuria, Semmola, M., 261.

Alcohol. Alcohol again: a consideration of recent misstatements of its physiological action, Warren, J. W., 1, 25; the disease of inebriety and its treatment, Crothers, T. D., 260; alcohol as an anæsthetic, Link, J. E., 313.

Alexander's Operation, Dolores, 334.

Allen, G. W. Cases of urethral endoscopy, 530, 537; cases of urethral endoscopy treated by electrolysis, 621, 630.

Amidon, R. W. Nervous symptoms from ocular defects; their relief by mechanical and medicinal measures, 497.

Amputation. Amputation at the hip-joint for the removal of a malignant growth, sarcoma, Dennis, F. S., 268, 286; when should amputation be practised, and when should other methods be employed? Lynde, U. C., 339; if amputation is to be performed, at what point should it be made to render the stump most useful, the risks to be encountered being equal? Bryant, J. D., 339.

Anæmia. A contribution to the study of pernicious anæmia, 90.

Anæsthesia. Alcohol as an anæsthetic, Link, J. E., 313; anæsthesia in normal labor, Kingman, R. A., 437.

Anatomy. Recent progress in anatomy, Dwight, T., 430.

Andrews, E. The removal of sequestra by solution in acid, 286.

Aneurism. A case of mesenteric aneurism, Whittier, E. N., 446.

Ankle-Joint. Discussion on the management of compound dislocation of the ankle-joint, Moore, E. M., 339; question of amputation, Lynde, U. C., 339; point of election, Bryant, J. D., 339; reduction of luxation, Brown, C. W., 339; dressing and after-treatment, Dennis, F. S., 339.

Annus Medicus, MDCCCLXXXVII, 631.

Antipyrine and Antifebrin. Antipyrine as an analgesic, 291; discussion upon the use of antipyrine and antifebrin in nervous disease, 413; antipyrine in sea-sickness, 516; the analgesic effects of antipyrine, Root, R. B., 558; poisoning from antifebrin, Bauer, F. M., 564.

Antiseptics. A brief note on the use of antiseptics in private obstetrical practice, Parvin, T., 385.

Aorta. A case of calcification of the aorta, Taylor, F. W., 578.

Aphasia without paralysis, Robinson, B., 510.

Aphorism. Medical aphorisms, 518.

Apostoli, G. The technique and treatment of uterine fibromata by electrolysis, 362.

Army Hospital Corps, 114.

Arnold, A. Fatty and dilated heart, 263.

Arnold, A. B. The practice of medicine at the present day, 238.

Arsenic. A case of poisoning from arsenical wall-paper, 476, 480.

Asaaky (Bucharest). Iodol, 287.

Athlete. Professor Sargent on the athlete, 439.

Atkinson, I. E. A clinical study of erysipelas in children, 232.

Austin Farm and the Suffolk County Insane, 340.

Ayer, J. B. Septicæmia from purulent inflammation of the portal vein (suppurative pylephlebitis), 536.

Bacillus. The death-point of micro-organisms, Sternberg, G. M., 94; bacteriology and its therapeutical relations, Semmola, 237; the cancer bacillus, 588; the discussion of the cancer bacillus before the Berlin Medical Society, 612; Scheurlen's cancer, 614.

Bacteria. Bacteriology and its therapeutical relations, Semmola, 237; antagonism among bacteria, Garré, C., 518.

Bantock, G. G. The treatment of the pedicle in supra-vaginal hysterectomy, 336, 363.

Barker, F. Address of welcome, 288.

Barnes, H. J. Milk-supply, 82.

Base-Ball. Injuries of base-ball players, Leuf, A. H. P., 69.

Battey, R. Battey's operation: its matured results, 364.

Bauer, F. M. Poisoning from antifebrin, 564.

Bayard, T. F. Address at International Medical Congress, 235.

Bell, A. N. The condition of the New York Quarantine indefensible, 519.

Benson, S. Fistula in ano of the horse-shoe variety, 285.

Benton, S. H. Antithermics in neuralgic pains, 560.

Bergeon. Clinical notes on Bergeon's treatment of chronic disease of the lung and air-passages by medicated gaseous enemata, Kinnicutt, F. P., 35.

Berlin. Letter from Berlin, 466.

Beasley. A case of purulent puerperal peritonitis successfully treated by puncture, 465.

Bibliography. American Gynæcological Society, transactions, 209; American Laryngological Association, transactions of eighth annual meeting, 63; Association of American Physicians, transactions, 1886, 18; same, 1887, 609; Anderson, T. McC., a treatise on diseases of the skin, 41; Bar, Paul, the principles of antiseptic methods applied to obstetric practice, 631; Barnes, R., and Barnes, F., a system of obstetric medicine and surgery, theoretical and clinical, 485; Bartholow, R., medical electricity: a practical treatise on the applications of electricity to medicine and surgery, 209; Bastin, E. S., elements of botany, 63; Battershall, J. P., food adulteration, and its detection with photomicrographic plates and a bibliographical appendix, 515; Boston City Hospital, annual report, 368; Butler, John S., the curability of insanity, and the individualized treatment of the insane, 630; Charcot, J. M., leçons sur les maladies du système nerveux, faites à la salpêtrière, 43; Charpentier, A., a cyclopædia of obstetrics and gynæcology: the four volumes on obstetrics, 585; Cutler, C. W., differential diagnosis of the diseases of the skin, for students and practitioners, 513; Dorsa, A. H. G., handbook of gynæcological operations, 537; Dowse, T. S., the modern treatment of disease by the system by massage, 461; Dujardin-Beaumetz, Prof., the modern treatment of diseases of the heart, Part II, 630; Field, H. M., evacuant medication, 437; Galabin, A. L., a manual of midwifery, 537; Gilbert, A., cancer massif du foie, 41; Goodell, W., lessons on gynæcology, 512; Hagar, A., Kaltenbach R., Winckel, F., and Breisky, A., cyclopædia of obstetrics and gynæcology, 365; Hartmann, A., the diseases of the ear and their treatment, 163; index catalogue, volume eight, 367; Jackson, G. T., a practical treatise on the diseases of the hair and scalp, 439; James, F. L., elementary microscopical technology, 163; Keating, J. M., practical lessons in nursing, 41; Keyt, A. T., sphygmography and cardiography, 340; King, A. F. A., a manual of obstetrics, 209; Klebs, E., die allgemeine pathologie oder die lehre von den ursachen und dem wesen die Krankenheits processe, 162; Ladd, G. T., elements of physiological pathology 65; Mann, M.D., editor, a system of gynæcology by American authors, 341; Marine Hospital Service, annual report, 612; Massachusetts, eighteenth annual report of the Board of Health, 163; Massachusetts, vital statistics for 1886, 391; Murrell, W., massage as a mode of treatment, 457; Ogle, W., anatomical research in the human rectum, and a new method of rectal inspection, 366; Pepper, W., editor, a system of practical medicine by American authors, 64; Robinson, T., the diagnosis and treatment of eczema, 513; Sanné, a treatise on diphtheria, historically and practically considered, including croup, tracheotomy, and intubation, 63; Sutton, J. B., ligaments: their nature and morphology, 64; Teisel, H. von, and Teisel, M. von, outlines of the pathology and treatment of syphilis and allied venereal diseases, 63; Thin, G., pathology and treatment of ringworm, 585; United States Pharmacopœia, dose and price labels, 113.

Bigelow, H. R. Carlsbad, 121, 148; Scheurlen's cancer bacillus, 614.

Biggs, H. M. Ruptured aortic aneurism, 268.

Biography. Allen, G. O., 372; Bogg, J. S., 72; Bird, G., 515; Carnochan, J. M., 442; Carr, A. F., 616; Chamberlain, W. M., 464; Clark, A., 296, 346; Cook, H., 394; Dana, D., 592; Drake, E. W., 24; Fassett, O. W. 120; French, J. O., 348; Hackett, C. W., 24; Hopkins, M., 68; Hutchinson, J. C., 93, 348; Hyde, F., 544; Knight, J., 442; Laugenbeck, R. K. von, 444; Linsley, J., 68; McArthur, J. A., 348; McGowan, C. E., 492; O'Gorman, 489; Parker, D. M., 372, 616; Putnam, S., 192; Quain, R., 372; Rowie, M. M., 21; Scott, J., 333; Smith, J. M., 616; Spring, C. H., 592; Stickney, P., D. B., 468; Tanner, N. B., 544; Ware, C. E., 244, 294; Waterman, J. H., 544; Webb, J. P., 296; Wilde, J., 396.

Blandford, G. F. The treatment of recent cases of insanity in asylums and private houses, 259.

Blodgett, A. N. An accident with cocaine, 282; a case of agoraphobia, 407, 409; antipyrine in case of carcinoma, 456; new instruments, 483.

Blood. The morphology of rheumatic blood, Cutter, E., 261.

Blue Color. Analysis of one hundred and forty-one cases of pregnancy, with reference to the diagnostic value of the blue color of the vagina, Farlow, J. W., 49, 58.

Boland, E. S. Symptoms following injury to the head and back, 450, 458.

Bone. A new method of operations on bone, Roberts, M. L., 311; the bones of the leg considered as one apparatus, Dwight, T., 593.

Boston. Table of fees in Boston in 1785, 516.

Bowditch, V. Y. Oxygen treatment in pneumonia, 582.

Boyland, G. H. Excessive heat the exciting cause of tuberculosis, 191.

Bozeman, N. A case of cystitis treated by colpo-uretro-cystotomy, irrigation of pelvis of the kidney, and intra-vaginal drainage, 340.
Brackett, E. G. The experimental value of the Dowse splint, 321, 360.
Bradford, E. H., and **Lovett, H. W.** Report on progress in orthopedic surgery, 503.
Brain. Operations on the brain, Horsley, V., 46.
Breast. A case of tumor of the breast, Mixter, S. J., 328, 359.
Bronson, E. B. Classification of diseases of the skin, 282.
Brooklyn, N. Y. Small-pox in Brooklyn: defective isolation and defective vaccination, North, N. L., 388.
Brown, C. W. Compound dislocation at the ankle-joint, 339.
Brown, D. Statistical records of intubation, 86; fatal case of vesical calculi, 583.
Brown, D. R. The treatment of pulmonary phthisis by the pneumatic cabinet, with a report of cases, 545.
Bryant, J. D. If amputation is to be performed in compound dislocation at the ankle, at what point should it be made to render the stump most useful, the risks to be encountered being equal? 339; how can the profession aid the Board of Health? 483.
Buckler, T. H. Excessive summer heat the exciting cause of tuberculosis, 118.
Buckley, L. D. Clinical notes on pruritus, 257.
Bull, C. S. Report of thirty-six cases of simple extraction of cataract without iridectomy, 108; the so-called orthopædic treatment of paralysis of the ocular muscles, 110.
Bullard, W. N. The relation of tea-drinking to disorders of the nervous system, 217.
Burnsky. The dietetics of mustard and pepper, 542.
Burnett, C. H. The successful removal of an exostosis from the external auditory canal by a new method, 89.
Burnett, S. M. Clinical contributions to the study of ring scotoma, 109; a modification of the refraction ophthalmoscope, with an attachment for using cylindrical-lens glasses, 184.
Burney (St. Louis). Gastrotomy for foreign bodies in the œsophagus, 288.
Burns. The treatment of burns, 91; cases of burns, with special reference to complications, sequelæ, and treatment, Cleaves, J. E., 501.
Burrell, H. L. Fracture of the spine: its immediate treatment by rectification of the deformity and fixation by plaster-of-Paris jacket, 169; four months' experience in minor surgery at the Boston City Hospital, 297, 309.
Burrell, H. L. and **Cushing, H. W.** Report on progress in surgery, 379, 403.
Busey, S. C. Cystocolpocele complicating labor and pregnancy, 290.
Cabot, A. T. Foreign body in Wharton's duct, 606.
Cæsarean Section by the bison's horn, 418.
Call, E. L. A case of chronic pancreatitis, with symptoms resembling malignant disease, 576, 581.
Calculi. Fatal case of vesical calculi, Brown, D., 583.
Calculus in Syria, Post, G. E., 311.
Cancer. The parasitic origin of cancer, 562; the cancer bacillus, 588.
Canedy, F. J., Grinder's consumption, 198.
Carlsbad, Bigelow, H. R., 121, 148.
Carminatives and the absorption of **gas** by the intestines, 214.
Carnochan. Bony union after intra-capsular fracture of the neck of the femur, 310; congenital dislocation of the heads of the femora, 312.
Carroll, A. L. Discussion on typhoid fever, 364; the clinical significance of sphygmographic tracings, 559; dressing for greenstick fracture of the clavicle, 561.
Cascara Sagrada, and its use in the treatment of constipation, Farlow, J. W., 402, 408.
Chadwick, J. R. Ventral hernia after laparotomy, and its surgical treatment, 362.
Cheever, D. W. The surgery of the abdomen, illustrated by eight cases, 6, 12; osteo-sarcoma of the scapula, 12.
Chemistry. Report on local chemistry, Hills, W. B., 453.
Children. Spontaneous absorption in empyema in children, and the relative advantage in children of aspiration and early incision, Holt, L. E., 14; acute empyema in children, Huber, F., 14; the use of meat as a regular article of diet in the nursery, Putnam, C. P., 30, 36; the artificial feeding of infants, Rotch, T. M., 305; the infantile uterus, Johnstone, A. W., 384; the prevention of chronic disease among the children of New York City, Leale, C. A., 206; a contribution to the study of the etiology of the summer diarrhœa of infants, Haven, H. C., 221; a clinical study of erysipelas in children, Atkinson, I. E., 232; a review of some of the more important papers presented to the section of children's diseases of the Ninth International Congress, Smith, J. L., 434; pertussis and its treatment by resorcin, Monteorvo, 435; cerebral irritation of young children, particularly of infants at the breast, Simon, J., 435; præputial dilatation, St. Germain, 435; ignipuncture of the tonsils, St. Germain, 436; reflexes in newly-born children, Farago, J., 489; sour milk for babes, Smith, J., 490; report on diseases of children, Rotch, T. M., 551.
Childs. Address in obstetrics, 38.
Chlorosis. Sir Andrew Clark on the causes of chlorosis, 565.
Cholera at the Port of New York, 317.
Cholera Morbus. The causation and treatment of cholera morbus, 340.
Circulatory System. Ruptured heart and thrombosis of the coronary artery, Sawin, 37; dilatation of the right ventricle and its exploratory puncture, Schrötter, 70; ruptured aortic aneurism, Biggs, H. M., 208; fatty and dilated heart, Arnold, A., 263; report on progress in diseases of the chest, Shattuck, F. C., 278; elastic constriction of the neck, with exclusion of the trachea, as a means of controlling hæmorrhage in operations on the head, Senn, 312; notes on hæmorrhagic infarction, Osler, W., 325; thrombosis of the portal vein, Osler, W., 336; a gun-shot wound of the heart, Formad, H. F., 337; septicæmia from purulent inflammation of the portal vein, Ayer, J. B., 536; a case of calcification of the aorta, Taylor, F. W., 578; case of pericarditis with complications, Read, I. B., 584.
Cirrhosis. Can cirrhosis follow trauma? a case of medico-legal interest, Stuart, W. F., 76, 81; experimental researches on the production of alcoholic cirrhosis of the liver, 188.
Clana, W. R. Typhoid fever, 261.
Clark, A. Resolutions on the late Alonzo Clark, M.D., 346.
Clark, A. Sir Andrew Clark on the causes of chlorosis, 565.
Clark, J. S. Disease in the milk-can, 160.
Clarke, J. W. An unusually rapid case of Graves's disease, 142.
Classification of diseases of the skin, Bronson, E. B., 282.
Clavicle. Dressing for greenstick fracture of the clavicle, Carroll, A. L., 561.
Cleaves, J. E. Cases of burns, with special reference to complications, sequelæ, and treatment, 501.
Club-Foot. Congenital talipes equino-varus, Scudder, C. L., 397, 424.
Cocaine. An accident with cocaine, Blodgett, A. N., 282.
Coe, H. C. The significance of pelvic pain, 511.
Cold. Methods of applying cold, 340; cold as a therapeutic agent, Hovey, B. L., 388.
Colorado Springs and Davos-Platz compared as health resorts Wagner, C., 458.
Colorado. Conditions favorable to out-of-door life in Colorado, Fish, S. A., 273; hints to physicians sending their consumptive patients to Colorado, Otis, E. O., 569, 579.
Colotomy. When is colotomy justifiable? Mathews, J. M., 264.
Colvin, D. Hæmorrhage in placenta prævia, 389.
Coma. A new means of detecting alcoholic and simulated states of coma, Wedekind, von, 294.
Congress. Congress of American Physicians and Surgeons, 417.
Consulting-Room. Dubray, 22.
Cook, C. H. Gall-stone, 410.
Cord. Spontaneous rupture of the cord, 142.
Corrosive sublimate in typhoid fever, Gläser, 46.
Creoline: a new disinfectant, Esmarch, F. von, 464.
Cronyn, J. Address on medicine, 387.
Croston, J. F. Local Boards of Health, 557.
Crothers, T. D. The disease of inebriety and its treatment, 260.
Cutaneous System. Treatment of diseases of the skin by medicated plasters, Shoemaker, J. V., 62; toxic effects of iodoform, Taylor, R. W., 231; a clinical study of erysipelas in children, Atkinson, I. E., 232; leucopathia unguium — a peculiar affection of the nails, Morison, A. B., 233; observation of three cases of simultaneous hand-and-foot disease, Hyde, J. N., 233; clinical notes on pruritus, Buckley, L. D., 257; clinical notes on pediculosis, Greenough, F. B., 257; an introduction to the study of the influence of diet on the causation and treatment of skin diseases, White, J. C., 258; the relations of dermatology to general medicine, Unna, P. G., 259; classification of diseases of the skin, Bronson, E. B., 282; the diagnosis of dermatitis herpetiformis, Duhring, L. H., 283; the treatment of leprosy, Unna, P. G., 283; the use of medicated rubber plasters in certain cutaneous diseases, Steiwagon, H. W., 284; salt in dermal hygiene and therapeutics, Piffard, H. G., 284; two cases of typical impetigo simplex, Duhring, L. H., 284; a case of purpura with circinate lesions, Steiwagon, H. W., 285; protest against excessive strength of local applications (officinal and others) in skin diseases, Sherwell, S., 285; the morbid changes and surgery of the nail, Foley, J. L., 301, 308; lupus serpiginosus of the cervix uteri and genitalia of women, Taylor, I. E., 338; report on dermatology, Tilbury, G. H., 551.
Cutler, E. G. Three cases of dyspepsia, 252, 255.
Cutter, E. The morphology of rheumatic blood, 261.
Cystitis. A case of cystitis treated by colpo-uretro cystotomy, irrigation of the pelvis of the kidney, and intra-vaginal drainage, Bozeman, N., 340.
Dana. On a case of anencephalitis illustrating the sensory tract, 185.
Dana (New York). Hereditary tremor, 134.
Davenport, B. F. Report upon food, drugs, and their examination, 53; tempora mutantur, 118; gleditschine-stenocarpine, 442; report on drugs, and their administration, 622.
Davenport, F. H. Uterine hæmorrhage: a consideration of some of the less common causes and their treatment, 124, 132; report of progress in gynæcology, 200.
Davidson. Cases of Addison's disease, 542.
Davis, W. W. The importance of early recognition, diagnosis, and surgical treatment of tumors of the bladder, 195.
Davis, N. S. Address at International Medical Congress, 236.
Davos-Platz. Colorado Springs and Davos-Platz compared as health resorts, Wagner, C., 458.
Dead Failure, limited, Garraway, E., 370.
Deafness. Is there a congenital sound-deafness? 586; word-deafness, 587.
Death by decapitation, 166.
Debaker, F. A new form of abdominal supporter, 263.
Dennis, F. S. Report of an amputation at the hip-joint for the removal of an enlargement growth, sarcoma, 268, 286; dressing and after-treatment in compound dislocation of the ankle-joint, 339.
Dentistry. Progress in dentistry, Rollins, W. H., 9.
Dercum (Philadelphia). Two cases of hemichorea associated with Bright's disease, 160.
De Reuyter (Berlin). The action of iodoform, 40.
Devalz. On the communicability of typhoid fever through the air, 190.
Diabetes, Pavy, F. W., 261.
Didama, H. D. Methods of applying cold, 340.
Diet. An introduction to the study of the influence of diet in the causation and treatment of skin diseases, White, J. C., 258.
Digestive System. Progress in dentistry, Rollins, W. H., 9; on the neurotic treatment of summer diarrhœa and cholera infantum, Harkins, A., 32; enterostomy for congenital atresia of the ilium, Tischendorff, 41; treatment of infantile dyspepsia by lactic acid: the causation of the greenish discharges which characterize this affection, 44; the causation and treatment of cholera morbus, 140; sepsis and antisepsis in summer diarrhœa, Potter, S. A., 175; membranous enteritis followed by intestinal perforation from ulcus rotundum, Rothmann, 190; carminatives and the absorption of gas by the intestines, 214; a new aid in the diagnosis of gastric disease, Ewald, 214; a contribution to the study of the etiology of the summer diarrhœa of infants, Haven, H. C., 221; three cases of dyspepsia, Cutler, E. G., 252, 255; diabetes, Pavy, F. W., 261; when is colotomy justifiable? Mathews, J. M., 264; gastrotomy for foreign

bodies in the œsophagus, Richardson, M. H., 267; fistula-in-ano of the horse-shoe variety, Benson, S., 285; remarks on rodent ulcer of the rectum, Norton, A. T., 285; chronic hypertrophic cirrhosis of the stomach, with gastric ulcer and colloid changes of the mucous membrane, Formad, H. F., 357; a case of acute dilatation of the stomach following laparotomy, Hunter, J. B., 361; membranous or pseudo-membranous enteritis, 390; gastralgia, 390; gastrotomy for the relief of cancer of the œsophagus, Warren, J. C., 434; igni-puncture of the tonsils, St. Germain, 436; prolapse of the rectum: treatment by the actual cautery, Packard, J. H., 446; a case of purulent puerperal peritonitis successfully treated by puncture, Besnier, 465; Rebra's cure for dyspepsia, 614.

Diphtheria. Diphtheria in Newmarket, N. H., Morse, 39; diphtheria and defective sewerage in the Massachusetts Homœopathic Insane Asylum at Westboro, 144; diphtheria, Grant, J., 262.

Diplomas. An M.D. in nine months, Fisk, S. A., 118; "shortcuts" to diplomas, Pengra, C. P., 271; "an M.D. in nine months," reply, Fisk, S. A., 346.

Dislocations. A case of double dislocation of the hip, Pfeiffer, O. J., 103; congenital dislocation of the heads of the femora, Carnochan, 312; discussion on the management of compound dislocation of the ankle-joint, Moore, E. M., 330; recent and neglected cases of dislocation of the radius and ulna upward and backward upon the humerus, Lynde, U. C., 364; a case of backward dislocation of the thumb upon the metacarpal bone, irreducible by manipulation: reduced by cutting down on the joint, Elliot, J. W., 625.

Dispensary, Boston, 394.

Doctor's Wife, Cœlebs, 566, 591; "Cœlebs," "Benedick," and "Gamboge," 614; doctor's wife, 637, 638.

Dolores (Paris). Alexander's operation, 334.

Dowse Splint. The experimental value of the Dowse splint, Brackett, E. G., 361.

Drainage after laparotomy, Mundé, P. F., 314.

Driver, S. W. Observations on the puerperal pelvic ligaments, 245.

Drugs. Report on foods, drugs, and their adulterations, Davenport, Bennett F., 622.

Druggist's Mistake, 490.

Dubray. The consulting-room, 22.

Duhring, L. H. The diagnosis of dermatitis herpetiformis, 283; two cases of typical impetigo simplex, 284.

Dwight, T. Recent progress in anatomy, 439; the bones of the leg considered as one apparatus, 593.

Dyspepsia. Three cases of dyspepsia, Cutler, E. G., 252, 255; Rebra's cure for dyspepsia, 614.

Ear. The examination of the power of hearing, and how to record its results, Knapp, H., 88; the successful removal of an exostosis from the external auditory canal by a new method, Burnett, C. H., 89; the differential diagnosis between affections of the middle ear and those of the labyrinth, Roosa, D. B. St. J., 89; remarks upon a case of cerebral abscess, Roosa, D. B. St. J., 90; suppuration of the tympanum occurring in a patient with Bright's disease, Roosa, D. B. St. J., 103; an efficient powder-blower, with remarks on the use of powder in the treatment of diseases of the ear, Holt, E. E., 104; excision of the ossicles of the drum of the ear for chronic purulent inflammation of the middle-ear tract, Sexton, S., 106; syphilitic disease of the labyrinth, Theobald, S., 107; remarks about the drum-membrane, with cases, Spear, E. D., 177, 183.

Editorials. The Fourth, 19; first annual meeting of the National Orthopedic Association, 20; State prophylaxis of syphilis, 42; treatment of infantile dyspepsia by lactic acid; the causation of the greenish discharges which characterize this affection, 44; the Boston Medical Library Association, 44; Kölliker's address before the German Anatomical Society, 66; report of the English committee of inquiry into Pasteur's treatment of hydrophobia, 67; the teaching of science by object-lessons, 68; a contribution to the study of pernicious anæmia, 90; the treatment of burns, 91; report of the Seybert Commission, 114; the doctrines of "Christian Science" and "Mind Cure," 114; academic and professional courses of study, 139; the causation and treatment of cholera morbus, 140; the eighteenth annual report of the State Board of Health of Massachusetts, 163; is genius a neurosis? 164; physical training for the police, 187; death after inoculation by the method of Pasteur, 188; experimental researches on the production of alcoholic cirrhosis of the liver, 188; paratrichites, 210; the abuses at Ward's Island Insane Asylum, 211; laparotomy for pelvic peritonitis and salpingitis, 212; the Fifth International Medical Congress, 241; the meeting of the International Congress at Washington, 269; antifebrin as an analgesic, 291; John Hunter as a syphilographer, 292; a grateful patient's estimate of the profession, 292; small parks as breathing-spaces, 293; the potato in its relation to Ireland's miseries, 315; transfusion and infusion, 316; cholera at the Port of New York, 317; hemiopia and the centres for vision, 342; house-flies as carriers of tuberculous contagion, 343; typhoid fever, 366; the index catalogue, volume eight, 367; a new method of treating sea-sickness, 397; annual report of the Boston City Hospital, 368; membranous or pseudo membranous enteritis, 390; gastralgia, 390; the vital statistics of Massachusetts for the year 1886, 391; the Army Hospital Corps, 414; another new treatment of tuberculosis by sulphurous acid fumes, 415; medicinal liquid vaseline, a new vehicle for hypodermic injections, 415; quarantine arrangements at the Atlantic sea-ports, 438; Professor Sargent on the athlete, 439; a second gastrotomy for the removal of a foreign body from the œsophagus, 461; the misquoting of medical men, 462; a case of sudden suppression of the visual memories, 462; the fifteenth annual meeting of the American Public Health Association, 486; a precursor of Pasteur, 487; the case of the Crown Prince of Germany, 487; naphthol as an antiseptic medicament, 488; sources of syphilis in the female, 513; uniformity in obstetric nomenclature, 514; the new Massachusetts "act concerning commitments and transfers of the insane," 514; on the psychology of joking, 515; the variations of the normal knee-jerk, 538; the doctor's wife, 538; on the pathogeny of sea-sickness, 539; Austin Farm, and the Suffolk County Insane, 540; the parasitic origin of cancer, 562; word-blindness, 563; is there a congenital sound-deafness? 586; faith-healing extraordinary, 586; word-deafness, 587; the cancer bacillus, 588; Stogdale *vs.* Baker, 610; the nerve-rest cure, 611; frequency of twin and triplet births, 611; annual report of the Marine Hospital Service, 612; the discussion of the cancer bacillus before the Berlin Medical Society, 612; Annus Medicus, MDCCCLXXXVII, 631.

Education. An M.D. in nine months, Fisk, S. A., 118; academic and professional courses of study, 139; another short cut into medicine, 143; the University of Michigan not guilty, 215.

Electrodes, Knapp, P. C., 309, 406.

Electrolysis. The technique and treatment of uterine fibromata by electrolysis, Apostoli, G., 362.

Elliot, J. W. A case of backward dislocation of the thumb upon the metacarpal bone, irreducible by manipulation: reduced by cutting down on the joint, 625.

Ellis, F. W. Description of a simplified clock-work apparatus for graphic experiments, 57.

Emmet, T. A. A study of the causes and treatment of uterine displacements, 288.

Empyema. Spontaneous absorption in empyema in children, and the relative advantage in children of aspiration and early incision, Holt, L. E., 14; acute empyema in children, Huber, F., 14; general consideration of the surgical treatment of empyema, Abbe, R., 15.

Endoscope. The endoscopic instruments of Joseph Leiter, of Vienna, and the present development of endoscopy, Newell, O. K., 528; cases of urethral endoscopy, Allen, G. W., 530.

Enteritis. Membranous or pseudo-membranous enteritis, 390.

Epilepsy. On trephining for epilepsy, Garmany, 288.

Erysipelas. A clinical study of erysipelas in children, Atkinson, I. E., 232.

Esmarch, F. von. Creoline: a new disinfectant, 464.

Ewald. A new aid in the diagnosis of gastric disease, 214.

Extra-Uterine Pregnancy. Report of a case of extra-uterine pregnancy, the fœtus being retained for thirty years, and becoming a lithopædion, Fales, W. H., 131, 133; extra-uterine pregnancy and its treatment by electricity, Van de Warker E., 386.

Eye. The pupil in its semeiological aspect, Macewen, W., 70; recent progress in ophthalmology, Standish, M., 78, 101; report of thirty-six cases of simple extraction of cataract without iridectomy, Bull, C. S., 108; report of a series of one thousand successive cases of extraction of cataract with iridectomy, Knapp, H., 108; does sunstroke affect the sight permanently? Spalding, J. A., 109; a case of poisoning by quinine amaurosis, Roosa, D. B. St. J., 109; clinical contributions to the study of ring sarcoma, Burnett, S. M., 109; the so-called orthopædic treatment of the ocular muscles, Bull, C. S., 110; hyperæmia in muscular insufficiency, Lippincott, J. A., 110; cases of primary glaucoma, of hæmorrhagic glaucoma, and of secondary glaucoma, Norris, W. F., 111; cases of glioma of the retina; prolapse of the lachrymal gland; operation for the relief of entropion of the lower eyelid, Noyes, H. D., 137; a phenomenal pulsation of the interior of the eye, Mittendorf, W. F., 138; increase of blindness in the United States, Howe, L., 138; the eye of the adult imbecile, Oliver, C. A., 157; additional cases of hypermetropia, the passing while under observation into myopia, Ripley, S. D., 157; the pathogenesis of pterygium, Theobald, S., 157; recurrent retinal hæmorrhages followed by the outgrowth of numerous small bloodvessels from the optic disc, Theobald, S., 157; embolus of the central retinal artery, Harlan, G. C., 158; a case of retinitis pigmentosa, Standish, M., 159; a septic cataract extraction with irrigation, Williams, C. H., 159; case of congenital zonula grayish-white opacity around the fovea, Wadsworth, O. F., 184; separation of the retina in both eyes, with albuminuria of pregnancy, Wadsworth, O. F., 184; set of small test-lenses, with a modified trial frame, Jackson, E., 184; ophthalmoscope with cylindrical lens, Risley, S., 184; a modification of the refraction-ophthalmoscope, with an attachment for using cylindrical-lens glasses, Burnett, S. M., 184; transient myopia following iritis, Green, J., 184; a comparison of some cases of cataract extraction, with and without iridectomy, Williams, C. H., 262, 285; hemianopsia, and the centres for vision, 342; the importance of re-examination as to the accuracy of vision of railroad employees and mariners, Williams, H. W., 373; enlargement and displacement of the lachrymal gland into the upper eyelid, Robertson, A., 465; nervous symptoms from ocular defects: their relief by mechanical and medicinal measures, Amidon, R. W., 497; a case of recurrent paralysis of the motor oculi, Wadsworth, O. F., 498; recent progress in ophthalmology, Standish, M., 601.

Faith-Healing extraordinary, 588.

Fales, W. H. Report on a case of extra-uterine pregnancy, the fœtus being retained for thirty years, and becoming a lithopædion, 133.

Farago, J. Reflexes in newly-born children, 489.

Farlow, J. W. Analysis of one hundred and forty-one cases of pregnancy with reference to the diagnostic value of the blue color of the vagina, 49, 58; cascara sagrada, and its use in the treatment of constipation, 402, 408.

Fees in Boston in 1785, 516.

Fell, G. E. Forced artificial respiration in opium-poisoning, 263.

Fernald, F. C. Puerperal insanity, 94.

Fever: its causes, mechanism, and rational treatment, Flint, A., 236.

Fibroid Tumors. The technique and treatment of uterine fibromata by electrolysis, Apostoli, G., 362.

Field, J. B. Was it mumps? 479.

Fingers. Skin-grafting and severed digits, Stephenson, F. B., 567.

Fisher. A case of bulbar paralysis, 186.

Fisk, S. A. An "M.D." in nine months, 118, 346; conditions favorable to out-of-door life in Colorado, 273.

Fistula-in-ano of the horse-shoe variety, Benson, S., 285.

Flies. House-flies as carriers of tuberculous contagion, 343.

Flint, A. Fever: its causes, mechanism, and rational treatment, 236.

Foley, J. L. The morbid changes and surgery of the nail, 301, 308.

Folsom, C. F. Early symptoms of general paralysis, 205.

Food. Foods, drugs, and their examination, Davenport, B. F., 33; the use of meat as a regular article of diet in the nursery, Putnam, C. P., 50, 36; milk-supply, Barnes, H. J., 82; disease in the milkcan, Clark, J. S., 100; the relations of tea-drinking to disorders of the nervous system, Bullard, W. N., 217; the artificial feeding of infants, Rotch, T. M., 305; sour milk for babes, Smith, J., 490; an introduction to the study of the influence of diet in the causation and treatment of skin diseases, White, J. C., 253; the dietetics of

mustard and pepper, Burjinsky, P., 542; report on foods, drugs, and their adulterations, Davenport, Bennett F., 622.

Foot. Chronic progressive caries of the foot, with cases and presentation of a patient, Walser, W. C., 560.

Foot and Mouth Disease. Foot and mouth disease as it affects man and animals, and its relations to human scarlatina as a prophylactic, Stickler, J. W., 607.

Formad, H. F. Chronic hypertrophic cirrhosis of the stomach, with gastric ulcer and colloid changes of the mucous membrane, 337; a stab-wound of the abdomen, 337; a gun-shot wound of the heart, 337.

Foster, F. P. Vaginal injections in Sims's posture, 387.

Fourth of July, 19.

Fractures. Family predisposition to fractures, Stüdensky, N. I., 22; bony union after intra-capsular fracture of the head of the femur, Carnochan, 310; ununited fracture of the femur successfully treated by double splice and mild clamp, Lemoyne, F., 311; splint for fracture of the lower jaw, Koser, S. S., 311; dressing for greenstick fracture of the clavicle, Carroll, A. L., 561.

Fraentzel. Creosote in tuberculosis pulmonum, 161.

Frederick, C. C. In cases in which the placenta is prævia, what anatomical and physiological facts explain the hæmorrhage occurring during pregnancy, and why is hæmorrhage unavoidable during miscarriage or labor? 388.

Frost, C. P. The germ theory, 38.

Frozen sections of the male pelvis, Strong, A. B., 311.

Future of Medicine, Pattee, 40.

Gall-Stones. Sabin, R. H., 340; gall-stone, Page, F. W., 410; Cook, C. A., 410.

Galvanism. The measurement of the galvanic current, with some remarks upon electrodes, Knapp, P. C., 399.

Galvano-Cautery Sound. The use of the galvano-cautery sound, particularly in hypertrophy of the prostate, with report of cases, Newman, R., 310.

Galvanometer. A new vertical galvanometer, Prince, M., 384.

Garmany. On trephining for epilepsy, 288.

Garraway, E. The dead failure, limited, 370.

Garre, C. Antagonism among bacteria, 518.

Gaseous Enemata. Clinical notes on Dr. Bergeon's treatment of chronic disease of the lung and air-passages by medicated gaseous enemata, Kinnicutt, F. P., 35; a report of ten cases of phthisis treated with gaseous enemata, Roeth, A. G., 51; carminatives and the absorption of gas by the intestines, 214.

Gastralgia, 390.

Gastrotomy. Gastrotomy for foreign bodies in the œsophagus, Richardson, M. H., 267; gastrotomy for foregn bodies in the œsophagus, Burney, 286; gastrotomy for the relief of cancer of the œsophagus, Warren, J. C., 434; a second gastrotomy for the removal of a foreign body from the œsophagus, 461.

Gaultheria. A case of poisoning with the oil of gaultheria, Pinkham, J. G., 548.

Generative System. Supplementary ovaries, Homans, J., 50, 58; uterine hæmorrhage: a consideration of some of the less common causes and their treatment, Davenport, F. H., 124, 132; report of progress in gynæcology, Davenport, F. H., 209; laparotomy for pelvic peritonitis and salpingitis, 212; a new sexual sedative, salix nigra, Hutchinson, S., 214; a series of intra-abdominal operations, Richardson, M. H., 225; observations on the puerperal pelvic ligaments, Driver, S. W., 245; some considerations upon the pathogenesis of diseases of women, Neftel, W. B., 262; three hundred and eighty-four laparotomies for various diseases, Homans, J., 263; a study of the causes and treatment of uterine displacements, 288; cystocolpocele complicating labor and pregnancy, Busey, S. C., 290; is salpingitis to be treated by extirpation of the tubes and ovaries in all cases? Polk, W. M., 313; the therapeutic value of some medicines in the treatment of hæmorrhagic conditions of the uterus, Palmer, C. D., 333; Alexander's operation, Dolores, 334; annual address before American Gynæcological Society, Skene, A. J. C., 335; the treatment of the pedicle in supra-vaginal hysterectomy, Bantock, G. G., 336; herpes serpiginosus of the cervix uteri and genitalia of women, Taylor, E., 338; the intra-uterine stem in the treatment of flexures, Jackson, A. R., 361; the technique and treatment of uterine fibromata by electrolysis, Apostoli, G., 362; ventral hernia after laparotomy, and its surgical treatment, Chadwick, J. R., 362; the treatment of the pedicle in supra-vaginal hysterectomy, Bantock, G. G., 363; Battey's operation: its matured results, Battey, R., 384; infantile uterus, Johnstone, A. W., 384; vaginal injections in Sims's posture, Foster, F. P., 387; a case of so-called "vicarious menstruation," Stuart, F. W., 474, 481; report on genito-urinary surgery, Post, A., 476; hydronephrosis supposed to be ovarian tumor, Weeks, S. H., 507; the significance of pelvic pain, Coe, H. C., 511.

Genius. Is genius a neurosis? 164.

Germany. The case of the Crown Prince of Germany, 487.

Germ Theory, Frost, C. P., 38.

Gibson. Wire extension-splints in the treatment of fractures near the joints, 311.

Glason (Hamburg). Corrosive sublimate in typhoid fever, 46.

Gmelin-Stenocarpine, Mattison, J. B., 419; Davenport, B. F., 442.

Hunter, J. John Hunter as a syphilographer, 292.

Hunter, J. B. A case of acute dilatation of the stomach following laparotomy, 361.

Hutchinson, J. A new sexual sedative, salix nigra, 214.

Hyde, J. N. Observation of three cases of simultaneous hand-and-foot disease, 233.

Hydronephrosis supposed to be ovarian tumor, Weeks, S. H., 507.

Hydrophobia. Report of the English committee of inquiry into Pasteur's treatment of hydrophobia, 67; death after inoculation by the method of Pasteur, 188; Pasteur's treatment, Whitmarsh, W., 528.

Hygiene, Health, and Boards of Health. The eighteenth annual report of the State Board of Health of Massachusetts, 163; Hygiene in French schools, 114; conditions favorable to out-of-door life in Colorado, Fisk, S. A., 273; how can the profession aid the Board of Health? Bryant, J. D., 483; local Boards of Health, Croston, J. F., 557.

Hypodermic Injections. Medicinal liquid vaseline, a new vehicle for hypodermic injections, 415.

Hysteria and hystero-epilepsy in soldiers, Jansen, 541.

Illusions. Illusions, hallucinations, and delusions, Jewett, M. A., 558.

Inebriety. The disease of inebriety and its treatment, Crothers, T. D., 260.

Infarction. Notes on hæmorrhagic infarction, Osler, W., 325.

Infection. Infectious nature of traumatic tetanus, Shakespeare, E. O., 256.

Injections. Inter-pulmonary injections in the treatment of phthisis, Smith, R. S., 261; vaginal injections in Sims's posture, Foster, F. P., 387.

Ingalls, W. High temperature from nervous causes, 557.

Insanity. The treatment of recent cases of insanity in asylums and private houses, Blandford, G. F., 259; the new Massachusetts "act concerning commitments and transfers of the insane," 514; illusions, hallucinations, and delusions, Jewett, M. A., 558.

Instruments and Apparatus. Description of a simplified clock-work apparatus for graphic experiments, Ellis, F. W., 57; set of small test-lenses, with a modified trial frame, Jackson, E., 184; ophthalmoscope with cylindrical lens, Risley, S. D., 184; a modification of the refraction ophthalmoscope, with an attachment for using cylindrical-lens glasses, Burnett, S. M., 184; a simple apparatus for rolling gypsum bandages, Wetherill, H. G., 204; a new form of abdominal supporter, Debaker, F., 263; wire extension-splints in the treatment of fractures near the joints, Gibson, 311; splint for fracture of the lower jaw, Koser, S. S., 311; the experimental value of the Dowse splint, Brackett, E. G., 321, 361; a new vertical galvanometer, Prince, M., 384; many-tailed bandage in fractures about the shoulder, Williams, E. T., 442; new instruments, Blodgett, A. N., 483; the endoscopic instruments of Joseph Leiter, of Vienna, and the present development of endoscopy, Newell, O. K., 528.

International Medical Congress. 234, 241, 242, 259, 269, 270, 285, 310, 319.

Iodoform. The action of iodoform, De Reuyter, 40; toxic effects of iodoform, Taylor, R. W., 231.

Iodol, Assaky, 287.

Intra-Uterine stem in the treatment of flexures, Jackson, A. R., 361.

Ireland. The potato in relation to Ireland's miseries, 345.
Irish, J. C. Laparotomy for pus in the abdominal cavity and for peritonitis, 145.
Jacobson, N. A contribution to the study of hip-joint disease, 338.
Jacoby, G. W. On microscopical studies in a case of pseudo-hypertrohic paralysis, 134; the treatment of neuralgia by means of intense cold, 185.
Jackson, A. R. The intra-uterine stem in the treatment of flexures, 361.
Jackson, E. Set of small test-lenses, with a modified trial frame, 184.
Jansen. Hysteria and hystero-epilepsy in soldiers, 541.
Jenckes, H. L. Atypical typhoid fever, with report of a case, 277.
Jennings, O. Detection of morphia-taking, 21.
Jewett, C. A note on the treatment of puerperal eclampsia, 387.
Jewett, M. A. Illusions, hallucinations, and delusions, 558.
Johnstone, A. W. The infantile uterus, 384.
Joints. Tuberculosis of the joints, Read, J. B., 59.
Joking. On the psychology of joking, 515.
Jones, C. D. Premature discharge of amniotic fluid, 71.
Jones, J. D. A case of acute lobar pneumonia with protracted first stage, 456.
Jurisprudence. Can cirrhosis follow trauma? a case of medico-legal interest, Stuart, F. W., 76; a case for the medical examiner, Presbrey, S. D., 411, 620.
Kelly, T. H. Hydrotheraphy in mental diseases, 187.
Kenefick, T. A. Maternal impressions on the fœtus in utero, 639.
Kidney. Injuries of and operations upon the kidney, Otis, E. O., 349, 360, 376.
Kingman, R. A. Anæsthesia in normal labor, 457.
Kinnicutt, F. P. Clinical notes on Dr. Bergeon's treatment of chronic disease of the lung and air-passages by medicated gaseous enemata, 35.
Kite, J. A. A case of rötheln occurring during the puerperium, 156.
Knapp, H. The examination of the power of hearing, and how to record its results, 88; report on a series of one thousand successive cases of extraction of cataract with iridectomy, 108.
Knapp, P. C. Recent progress in diseases of the nervous system, 303; the measurement of the galvanic current, with some remarks upon electrodes, 389, 409.
Knee-Jerk. The variations of the normal knee-jerk, 538.
Knee-joint. Four cases of penetrating wound of the knee-joint treated at the Boston City Hospital, Howe, O. H., 549.
Knight, F. I. Is tuberculosis of the lungs ever contagious? 19, 81.
Kolliker's address before the German Anatomical Society, 66.
Korosi, J. The preventive power of vaccination for small-pox, 238.
Koser, S. S. Splint for fracture of the lower jaw, 311.
Lamalleree. A case of tuberculosis infection, 93.
Laparotomy. Laparotomy for pus in the abdominal cavity and for peritonitis, Irish, J. C., 145; laparotomy for pelvic peritonitis and salpingitis, 212; three hundred and eighty-four laparotomies for various diseases, Homans, J., 263; an important point in abdominal surgery, Hewson, A., 264; three cases of lapar-o-nephrectomy, Maclain, D., 266; drainage after laparotomy, Mundé, P. F., 314; a case of acute dilatation of the stomach following laparotomy, Hunter, J. B., 361; ventral hernia after laparotomy, and its surgical treatment, Chadwick, J. R., 362; laparotomy for tubercular peritonitis, 217.
Larynx. Report on progress in laryngology and rhinology, Hooper, F. H., 53; intubation of the larynx, Hubel, F., 85; feeding after intubation of the larynx, O'Dwyer, J., 86, statistical records of intubation, Brown, D., 86; pathological anatomy of the respiratory tract after death from laryngeal diphtheria and intubation, Northrup, W. P., 87; case of laryngotomy after intubation, Hance, J. H., 87; the conversion of benign growths of the larynx into malignant, Schnitzler, 613.
Lead. On the frequency with which lead is found in the urine, and on certain points in the symptomatology of chronic lead-poisoning, Putnam, J. J., 73, 97; lead-poisoning as a cause of muscular coördination (pseudo-tabes), Putnam, J. J., 596, 605.
Leale, C. A. The prevention of chronic disease among the children of New York City, 206.
Leg. The bones of the leg considered as one apparatus, Dwight, T., 565.
Lemoyne, F. Ununited fracture of the femur successfully treated by double splice and wire clamp, 311.
Leprosy. The treatment of leprosy, Unna, P. G., 283.
Leuf, A. H. P. Injuries of base-ball players, 69.
Library. The Boston Medical Library Association, 44.
Lichtheim (Bernie). A contribution to the study of pernicious anæmia, 90.
Lincoln, D. F. The climate and health of Savannah, 427.
Link, J. E. Alcohol as an anæsthetic, 313.
Lippincott, J. A. Hyperæmia in muscular insufficiency, 110.
Liver. Experimental researches on the production of alcoholic cirrhosis of the liver, 188; report of some cases of liver abscess and their treatment, Grant, 286; a case of acute red atrophy of the liver, Holt, A. F., 374, 383.
Lloyd. Notes on a case of the insanity of doubt, 135.
Lopez, M. A case of tetanus cured by hypodermic injections of cocaine, 21.
Lusk, W. T. If placenta prævia be diagnosticated during pregnancy, is the induction of premature labor indicated? 389.
Lynde, U. C. When should amputation be practised in compound dislocation at the ankle, and when should other methods be employed? 339; recent and neglected cases of dislocation of the radius and ulna upward and backward upon the humerus, 364.
Lyon, S. B. Melancholia due to the prolonged use of morphia, 412.
Macewen, W. The pupil in its semeiological aspect, 70.
Malaria, Tomassi-Crudelli, 117.
Malt. The therapeutic value of malt, Townsend, C. W., 353.
Manley, T. H. Gun-shot wounds of the abdomen, 310.
Many-tailed bandage in fractures about the shoulder, Williams, E. T., 442.
Marcy, H. O. Ninth International Medical Congress, Gynæcological Section, 319.
Massage. Local massage for local neuralgia, Graham, D., 573, 581.
Materia Medica. Alcohol again: a consideration of recent misstatements of its physiological action, Warren, J. W., 1, 25; a case of tetanus cured by hypodermic injections of cocaine, Lopez, M., 21; report on food and drugs and their examination, Davenport, B. F., 33; the action of iodoform, De Renyter, 40; corrosive sublimate in typhoid fever, Gilliser, 46; respiratory therapeutics in the treatment of phthisis pulmonalis, MacNamara, L. J., 60; treatment of diseases of the skin by medicated plasters, Shoemaker, J. V., 62; palatable therapeutics, Greene, T., 62; creosote in the treatment of tuberculosis pulmonum, Fraentzel, 161; the treatment of neuralgia by means of intense cold, Jacoby, G. W., 185; hydrotherapy in mental diseases, Kelly, T. H., 187; paratriptics, 210; carminatives and the absorption of gas by the intestines, 214; toxic effects of iodoform, Taylor, R. W., 231; an accident with cocaine, Blodgett, A. N., 282; the use of medicated rubber plasters in certain cutaneous diseases, Stelwagon, H. W., 284; salt in dermal hygiene and therapeutics, Piffard, H. G., 284; protest against excessive strength of local applications (officinal and others) in skin diseases, Sherwell, S., 285; the removal of sequestra by solution in acid, Andrews, E., 286; iodol, Assaky, 287; antifebrin as an analgesic, 291; alcohol as an anæsthetic, Link, J. E., 313; report on progress in therapeutics, Williams, F. H., 329, 355; the therapeutic value of some medicines in the treatment of hæmorrhagic conditions of the uterus, Palmer, C. D., 333; the use of hot water in surgery, Varick, T. R., 338; bichloride of mercury: its uses and abuses, Wood, C. S., 338; the therapeutic value of malt, Townsend, C. W., 353; cold as a therapeutic agent, Hovey, B. L., 388; cascara sagrada and its use in the treatment of constipation, Farlow, J. W., 402, 408; melancholia due to the prolonged use of morphia, Lyon, S. B., 412; discussion upon the use of antipyrine and antifebrin in nervous disease, 413; another new treatment of tuberculosis by sulphurous acid fumes, 415; medicinal liquid vaseline, a new vehicle for hypodermic injections, 415; strychnia in seasickness, Hubbard, R., 418; gleditschine-stenocarpine, Mattison, J. B., 419; Davenport, B. F., 442; creoline, a new disinfectant, Esmarch, F. von, 464; naphthol as an antiseptic medicament, 488; antipyrine in sea-sickness, 516; mercurial washes sometimes dangerous, Pepper, A., 517; the analgesic effects of antipyrine, Root, R. B., 558; antithermics in neuralgic pains, Benton, S. H., 560; discussion on the uses of hyoscyamine, 631.
Mathews, J. M. When is colotomy justifiable? 264.
Mattison, J. B. Gleditschine-stenocarpine, 419.

ALCOHOL AGAIN: A CONSIDERATION OF RECENT MISSTATEMENTS OF ITS PHYSIOLOGICAL ACTION.

BY JOSEPH W. WARREN, M.D.
Assistant in Physiology in the Medical School of Harvard University.

THE friends of temperance, falsely so-called, since total abstinence, and usually prohibition, are meant, are persistent distributers of printed matter, by which they hope to convince, or, at least, to influence their neighbors. Quite recently, such a tract on "Alcoholic Liquids as Therapeutic Agents" was extensively circulated in this vicinity, and doubtless in other places. Were it merely a pamphlet issued by the "Woman's Temperance Publication Association" of Chicago, and distributed hereabouts by the "Boston Women's Christian Temperance Union," any criticism might seem superfluous. But the tract is more than this: it is the reprint of a chapter of a medical work,[1] and, moreover, this chapter is said to have constituted a special lecture, "the closing lecture in the Practitioner's Course for 1884, and was given in compliance with a special request of the class in attendance." As a teacher's statement of the truth about alcohol, as the declaration of an older and prominent physician to younger men just entering the profession, this lecture may very properly attract our attention and criticism, since it is full of error and misstatement concerning the physiological action of alcohol, and the therapeutic inferences drawn therefrom are, to say the least, most doubtful.

It is for this reason that I venture to reopen the question, and to give a brief summary of the chief points of our knowledge of the physiological action of alcohol and alcoholic beverages. And I will say here, for the benefit of any multiscient reader, that while I hope to put together the best and the freshest of our knowledge, I have nothing absolutely *new* to give. While I shall endeavor to make due acknowledgment to the men whose labors have been chiefly valuable in establishing experimentally that portion of our knowledge which has such foundations, it would be as impracticable as it would be tiresome and unprofitable to name every experiment which has been made. Merely to give the enormous literature of the subject, would make a long article.

I. It is generally supposed that alcohol introduced into a sound stomach, in a not too concentrated form, is absorbed *unchanged*. The evidence that a portion is oxidized in the stomach or intestine is not strong; in any case, the amount thus altered must be exceedingly small. If the intestinal tract is affected by catarrhal or other disturbance, the absorption of dilute alcohol will be delayed or prevented, just as that of any liquid would be hindered. On this point, everybody is in substantial accord with the tract. Whether the absorption be altogether by the blood, is open to further investigation. The function of the leucocytes has been so much extended recently, that it would be hasty to deny them a share in the absorption of any substance that passes from the intestine into the body, and Dogiel claims to have demonstrated the presence of alcohol in the thoracic duct very soon after it has been taken into the stomach. The introduction of alcohol into the body appears to stimulate various glands, so that the flow of saliva is increased, and, apparently, that of the gastric juice as well. The immediate effect on any digestion which may be going on has been the subject of much experimental inquiry. The observations which have been made with artificial digestions have generally been unfavorable to any admixture of alcohol, certainly to any considerable one. The experiments of Ogáta[2] on a dog with a fistula also seemed to show that alcoholic beverages cause a delay in the digestive process. The very recent investigations of Gluzinski[3] shed light on the discrepancy hitherto existing between these experimental results and the clinical experience that a sluggish digestion is often favorably affected by a little alcohol. Gluzinski found that, while the presence of alcohol does retard the digestive process (as shown by examination of the substances which can be pumped out of the stomach), the alcohol is rapidly absorbed, and the digestion is then accelerated, on account of an increased secretion of gastric juice. This taking place all the more readily in an empty stomach, would explain the good effects of alcohol in this connection.

II. The alcohol which has been absorbed does not leave the body in any considerable quantity as alcohol, nor as the more immediate products of oxidation (aldehyde or acetic acid). This is, perhaps, the most important truth, and has been most exactly established. It is unfortunate that Dr. Davis has again denied it. He says, page 4 of the tract: "The experimental researches of Lallemand, Perrin, and Duroy proved conclusively that alcohol . . . was eliminated as alcohol, unchanged chemically, from the lungs, skin, and kidneys," and he adds cautiously, a few lines later, that these experiments have been confirmed, "except the claim that the amount eliminated is not equal to the whole quantity taken." Surely, no beginner would infer from the last quotation that *every* competent investigator had found the amount eliminated to be not only "not equal to the whole quantity taken," but really to form only a small fraction of it; yet such is actually the case. This misstatement is aggravated by being followed a little later by another, and perhaps worse one, concerning Anstie's conclusions on the question of elimination.

The researches of the French authors mentioned above[4] have acquired the distinction of serving as the chief weapon of the opponents of alcohol. Their apparent exactness has recommended them to many, and has rendered it difficult to give a complete and convincing demonstration of the falsity of the most important conclusion of the book: "*L'alcool est éliminé de l'organisme en totalité et en nature*" (p. 233). If the reader will take the trouble to examine the experiments on which this conclusion is based, he will be astonished at the weakness of the evidence. If he will also reckon out the amounts of alcohol which it was considered necessary to give to dogs in these investigations, and then state these amounts for a man of average weight, his astonishment will in no wise be diminished.[5] Now it may be very instructive

[5] It appears from the memoranda, on pages 47, 57, 63, and 66 of the above work, that an amount of alcohol equivalent to a whole bottle of brandy for an average man was a common dose for the dogs. In

to know just how much alcohol a dog can take and live — or die; to infer the physiological action from these amounts is dangerous; but, as we shall see presently, these investigators, in using such doses, have, in several instances, dug a pit for their own destruction.

When we recall how soluble alcohol is, and the ease with which it is absorbed, it need not seem strange that some should be excreted through the ordinary channels. It does not commonly surprise us that water is excreted, or salt, and we do not venture to build up enormous hypotheses on these facts. No one is ever restrained from using the iodide of potash because of the wonderful speed with which a portion is eliminated, and nowadays, the occasional presence of even a little albumin in the urine is looked upon with great complacency. We ought, then, to be very cautious in drawing hasty conclusions from the partial elimination of alcohol, which undoubtedly often takes place. The question which really concerns us is the amount of alcohol thus disposed of.

I ought to add, in passing, that the work of Subbotin[6] is sometimes quoted, as showing positively a considerable excretion. It has, however, been very properly urged that he only used rabbits in his experiments, and gave them enormous doses of alcohol, so that his results do not really demonstrate its physiological action.

The most careful and extended experiments to determine the amounts of alcohol which pass off through the lungs, the skin, and the kidneys are those undertaken in England by Anstie chiefly, or at his suggestion, and those made by Binz and his pupils in the Pharmacological Laboratory at Bonn. It is, however, worthy of notice, that the work of Lallemand, Perrin, and Duroy, which led to this long controversy, contains its own refutation in itself,[7] and was speedily objected to in its own country (Baudot). The methods for determining the excretion are not all as exact as is desirable. The simplest, (the iodoform test and the test by the reduction of chromic acid)[8] permit the establishment of an upper limit as to the amount of the excretion but do not give an exact quantitative determination. The inflammability or the odor of the products of distillation is obviously the most uncertain of tests as regards quantity. Much more exact would appear to be the determination with the vaporimeter which has been used more extensively at Bonn than in England.

It would require too much space to give the details of the English and German researches. To some extent they may be considered to supplement each other since the latter have developed the quantitative methods more fully, while the careful work of the former has established certain other points very completely, although more indefinitely as to quantity. Anstie[9] and his fellow-workers found that under the most varying conditions and with the use of all sorts of alcoholic beverages, the amount excreted, by dog or man, through all the channels already mentioned, was invariably small. Although Anstie's views are expressed with such perfect clearness in the publications just mentioned, that he who runs may read, Dr. N. S. Davis ventures to twist them as follows (Tract, p. 4); "The late Dr. Anstie, who followed up the investigation of this question with the most commendable perseverance, came to the conclusion that an average-sized adult in ordinary health, was capable of retaining about forty-five grammes (fl. ℥iss) of pure alcohol in the twenty-four hours, admitting that whenever more than this was taken in the time specified, it re-appeared in the evacuations, or was eliminated unchanged." But Anstie's "admission" consisted in the declaration that "the total amount eliminated, however, even in these cases, (that is, for more than ℥iss), was very small." For ℥iij-iv he could never find more than one or two grains in the urine.

Anstie's efforts were ably seconded by Dupré, who in a number of researches showed that the amount of alcohol excreted daily (and which he found to be altogether a minute fraction only of the amount taken), does not increase with the continuance of the alcohol diet, and he showed furthermore, (*contra* Parkes and Wollowicz) that this elimination is practically finished in twenty-four hours after the alcohol is taken.[10] Dupré's experiments have also a peculiar interest because he found that after abstaining from alcohol for ten days he still eliminated a substance through the kidney which when oxidised by chromic acid, yielded a volatile acid having the smell of acetic acid, and therefore simulating the excretion of alcohol as determined by this reaction. But the urine of a teetotaler who had but once in his life taken alcohol, and that two years previously, contained a similar substance at various times!

The work done in reference to this question at Bonn, has yielded quite a literature,[11] and its latest contribution[12] is the result of such careful experimentation under control of the vaporimeter as to leave no possible doubt concerning the amount of alcohol commonly excreted from the body, and I venture to remind the reader that it appeared some months before the delivery of the lecture forming the tract we are considering. I must refer the reader to Bodländer's article for the details of the experiments made on himself and on a

one experiment, the equivalent was as much as two and one-half bottles, and in another case, *three* bottles of brandy.

[6] Subbotin. Ueber die physiologische Bedeutung des Alkohols für den thierischen Organismus. Ztschr. für Biologie, 1871, vii., 381. See Dupré's severe, but just, criticism in the Practitioner, Vol IX, page 28.

[7] The amount recovered, for example, in the urine collected from several men for four hours after the consumption of three bottles of Burgundy and 120 grammes of Cognac, is by a most liberal calculation, less than 1 per cent., (probably not more than 0.4 per cent.) The amount obtained in the respiration experiments, so far as it can be calculated, does not seem to make a much better showing.

[8] Of these the iodoform reaction (which arises on heating dilute alcohol with a solution of iodine in the iodide of potassium decolorized with sodic hydrate) is especially untrustworthy, since carbohydrates, albumin, fibrin, etc., also form iodoform under similar conditions. Although this source of error was made known by Millon, as early as 1845, it was commonly overlooked by later investigators. It has also been found (Lieben) that perfectly normal dog urine contains substances which can be distilled off and give the iodoform reaction. Rajewsky (Pflüger's Archiv., xi. 129), observed that the distillation of perfectly fresh muscles (horse) or liver (horse or dog) or of the brain of a rabbit which had eaten nothing for two days, produced substances which gave this reaction, and, strangest of all, these tissues actually seemed to also contain very small amounts of alcohol. And the test with chromic acid or the bichromate of potash in sulphuric acid, although very delicate, is unfortunately not limited to alcohol. Aldehyde, acetic acid, and many other substances produce the same color change and may be mistaken for alcohol.

[9] The reader will find a sufficient account of this work in Anstie's Stimulants and Narcotics, 1864, and more especially in his "Final experiments on the elimination of alcohol from the body," in the Practitioner, 1874, xiii, 15. The latter article reviews the course of the English researches on the subject, and is particularly interesting because the author died about two months after its publication.

[10] Dupré, "On the Elimination of Alcohol." Proceedings of the Royal Society, 1871, xx, 268. The substance of this paper may also be found in articles in the Practitioner, viii, 148, 224.

[11] Its results are reported in several dissertations and in articles by Binz, who has also briefly collated it in Lectures xxix and xxx, of his recent "Vorlesungen über Pharmakologie." See also Binz, Die Ausscheidung des Weingeistes durch Nieren und Lungen. Arch. f. exp. Path. u. Pharm., vi, 287, and Heubach, Quantitative Bestimmung des Alkohols im Harn, in the same Archiv, viii, 446.

dog. It took 50–100 cm. absolute alcohol diluted with water, equal to two-thirds to four-thirds of a bottle of claret. The dog received rather large doses, 10 to 30 cm. alcohol, or the equivalent of one and one-third to four bottles of claret for an average man. The amounts recovered may be tabulated as follows:

Excreted by	Dog. Experiments	Dog. Avge. Recov'd	Man. Experiments	Man. Avge. Recov'd	Remarks.
Kidneys	4	1.58%	12	1.18%	The chief excretion is during first hour, and is usually reduced to zero after three hours, provided the bladder has been fully emptied.
Skin	2	0	3	0.14	The excretion by the skin is practically over in four hours.
Lungs	3	1.95	3	1.60	The lung excretes alcohol much longer than the other organs, but the amount is small.
Intestines	....	....	1	0	Parkes' determination of alcohol in this connection, was made with faeces which had been preserved several days, so that many fermentative changes may have taken place.
		3.53%		2.92%	

The only other probable path of elimination would be the mammary gland, but experiments with this has led to negative results, and the stories about the intoxication of infants by means of the mother's milk are probably fables.[13]

Bodländer's results for the kidney excretion are in substantial agreement with those of Heubach [14] from the examination of the urine of various fever patients, who had received considerable doses of alcohol (18.0 to 325 ccm.) in different forms. The average output through the kidneys for 22 experiments was 1.12 per cent., or possibly 1.5 per cent., on account of errors in the method.

Even if we allow 10 per cent. for a possible error in the method of Bodländer (and the error of the vaporimeter is not greater than this) we shall find that less than 5 per cent. of the alcohol taken into the body is excreted by the ordinary channels during the entire time that delicate tests show the excretion to continue. In other words, it appears *that at least 95 per cent. of any reasonable amount of alcohol introduced into the animal body by the stomach, disappears, and is not found in the excretions, either as alcohol or as its more immediate oxidation products (aldehyde or acetic acid)*. This is result not merely of Bodländer's work but of Anstie's and of the experiments of many others. All experimental results of a contrary nature are either inexact in methed or have been arrived at by the use of quantities of alcohol so large as to be considered unreasonable.

III. The alcohol which is taken up into the body and not excreted disappears; it is transformed in some way not made out as yet, and *is not stored up as alcohol.*

[13] See Bodländer, op. cit., p. 425.

[14] See also Heubach, Ueber die Ausscheidung des Weingeistes durch den Harn bei Fiebernden. Inaug-Diss. Bonn, 1875.

This is evident from a number of considerations which have an experimental basis. In the first place, the determinations of Anstie and Dupré showed that the excretion does not increase when the alcohol diet is continued, as it might be expected to do if the alcohol remained in the body as alcohol. Should it be urged that this excretion is already the greatest possible, it would be well to consider an experiment made by Anstie [15] in 1873. He gave a small dog (9¾ pounds) one ounce of brandy (containing 198.9 grains of alcohol) daily for a number of days. The excretion on the tenth day was only 1.13 grains of alcohol. On the eleventh day, two hours after receiving half-an-ounce of brandy, the dog was killed, and very rapidly cut up into very small pieces, and every fragment of the animal was put into water for extraction. A few hours later this mixture was examined, and only twenty-four grains of alcohol could be recovered, or not more than one-fourth of the amount which had been taken but a couple of hours before. Remembering that the elimination of the previous day was only 1.13 grains, we must infer that the dog had used up some eleven ounces of alcohol with great completeness. This corroborates an earlier discovery made by Schulinus and Sulzynski, pupils of Buchheim.[16] In the course of some experiments showing that little alcohol is excreted, and that the blood contains, relatively, rather more than other tissues, it was found that fresh blood causes a portion of the alcohol which has been added to it to disappear. The loss seems to be, at least, ten per cent. This is in some way a "vital" phenomenon of the blood, for blood which has been carefully kept from eighteen to twenty-four hours disposes of much less alcohol, apparently less than one per cent. Lallemand, Perrin, and Duroy [17] held that the alcohol accumulated in the blood, but especially in the brain and liver. Their figures for the amount in the liver permit no convincing calculation of the proportion of the alcohol to be found in that organ. As to the brain and the blood, such statements as are so made as to permit a calculation, show that, although very large doses were given, not more than one per cent. of the alcohol was found in the brain (experiments with six dogs), and not more than eleven per cent. in the blood (experiments with two dogs). A still further incidental corroboration of the disappearance of alcohol I shall refer to later.

I do not see how the conclusion can be avoided that alcohol is disposed of as really and as truly as any food. In fact, if we could consider its behavior as thus far presented without any bias whatever, I doubt if any one would hesitate to call alcohol a food.

I venture to place here the almost pathetic words with which Anstie closed the report of his "Final Experiments," which were, unfortunately, to be really final for him:

"I therefore trust that we may consider one important portion of the alcohol question to be closed. It is certainly rather hard that the very inadequate researches of Lallemand, Duroy, and Perrin should have been allowed so long to mislead the majority of the profession and of the public upon the subject of the elimination of alcohol, being, as they were, mere qualitative experiments, and, even as such, devised and

carried out with such an absence of all reasonable precaution against fallacy, as should have set physiologists on their guard at once. As it is, it has cost some fourteen years of almost unintermittent work to explode the errors which the French observers made current respecting a merely preliminary investigation into the action of alcohol. I appeal to the respectable members of the teetotal party, and I put it to their sense of honor not to continue to circulate the gross misstatements on this subject which, even now, are circulated broadcast in the tracts with which their society floods the country. It cannot do the temperance cause any good in the end; indeed, the discovery that they have been systematically misled on a point to which their informers could have no difficulty in ascertaining the truth, has already produced a strong revulsion in the minds of many persons against everything that bears the most distant relation to teetotalism."

Nearly another fourteen years have passed since these words were written, and yet the same misstatement continues.

IV. Various practical considerations have led physiologists, as well as pharmacologists, to examine the influence of alcohol, particularly on the body temperature, on the heart, and on the transformation and tissue changes in the body, which are now very commonly called its metabolism.

Historically, it seems to have been chiefly the favorable results obtained by the use of large doses of alcohol in the treatment of fevers, especially in England, and there particularly under the leadership of Todd, which directed attention to the question of temperature and eventually to the other points of inquiry. The well-known "warming" effect of alcoholic drinks which manifests itself at first in the epigastric region, "making glad the heart of man" seemed at variance with its favorable action on fevers. It was thought by theorists that alcohol ought to raise the temperature and so be harmful in fever, but careful investigation has shown that alcohol tends to lower the temperature of the body. Dr. Davis (page 3 of our tract) suggests that this knowledge is due to him, having been demonstrated in experiments which he made in 1850, and used in a paper[18] read before the American Medical Association in May, 1851. As there detailed his experiments prove nothing of the kind. He mentions *two* experiments made apparently with no control experiments whatever, and showing a fall of 0.5° F., which is attributed to the brandy taken. When we remember that these observations were made between nine and eleven o'clock at night, in other words, at a time when the temperature would naturally sink, we shall see how little credit is to be attached to them. Not only were Dr. Davis's observations quite inconclusive, but they are not even the earliest. A couple of years before, Duméril and Demarquay[19] had demonstrated that alcohol causes a very considerable lowering of the temperature. Their method was not altogether unobjectionable; the control experiments do not appear to have been sufficiently numerous, and the doses were very large. Still earlier Nasse,[20] had observed a fall of temperature in rabbits, but he laid no stress upon it.

Here, again, the Bonn pharmacological laboratory has been active in making the measurements required to clear up this question.[21] The fact is, that it is not always quite as easy to affect the temperature by alcohol as many who are but partially familiar with the subject commonly suppose. All careful investigators are agreed that alcohol taken into a healthy animal body never raises the temperature. As to the lowering, the following statement, condensed from Binz (Vorlesungen, page 360), gives the view which has a good claim to general acceptance: The temperature of healthy persons is not sensibly altered by small amounts of alcohol, which, however, may be large enough (particularly in a concentrated form) to produce a feeling of warmth in the stomach and later in the skin. Moderate amounts of alcohol, 30 to 80 grammes, (that is, two-fifths to one bottle of claret), may cause the temperature to fall 0.3° to 0.6° C. (0.5° to 1.1° F.)and this without the production of intoxication. This reduction of the temperature is also evident at the time of day when a rise would be naturally expected, (Daub), but the amount of the reduction is very much lessened by the habit of using alcohol. Narcotic doses, on the other hand, reduce the temperature several degrees and this continues for some hours. In other words, a glass of whiskey or a pint of beer has no appreciable effect on the body temperature; doubling the dose will perhaps cause the temperature to fall somewhat in those unaccustomed to the practice; complete intoxication (from alcohol) is accompanied by a great fall of temperature.[22]

The conclusions of Ringer and Rickards[23] and those arrived at by Parkes[24] are in substantial agreement

The literature is very fully given in Binz's "Vorlesungen" including several dissertations which I omit.

[22] And this fall is all the greater when the drunkenness happens to coincide with exposure to cold. Several illustrations of this have become classic:

See: Magnan, Gaz. méd de Paris, 1870, 88: "Une femme ivre, qui était restée pendant plusieurs heures exposée à un froid très-vif, a présenté au rectum à l'aisselle une température de 26°, (78.8° F.) qui s'est élevée progressivement, de huit heures du matin à quartre heures du soir, jusqu' à 37°, température normale. La malade, du reste, est sortie guérie de l'hôpital."

Reincke, Beobachtungen über d. Körpertemperatur Betrunkener. Disch. Archiv. f. kl. Med., 1875, xvi, 12. These were cases brought in by the police. Temperatures from 30° to 35.4° C. (86° to 95.7° F.), were common. In some lethal cases it was still lower. His most extraordinary temperature (p. 15), was in a man who was found drunk shortly after midnight. He was transferred to the hospital in the morning with a rectal temperature at 8 o'clock of 24° C. (75.2° F.) There was gradual improvement during the day and at 7 o'clock the next morning the temperature was normal and he was discharged at noon.

Weckerling, same Arch., 1877, xix. 317. Rectal temperature of 35.4° C., (95.7° F.) in a child (three and three-quarters years), which had drunk a large quantity of "schnaps."

[23] Ringer and Rickards. Influence of Alcohol on the Temperature of Non-febrile and Febrile Persons. 1866. Proc. Roy. Med. and Chir. Soc., v. 209.

[24] See: Lond. Med. Rec., 11 Mch. 1874. Parkes' chief contributions which bear on this point are:

(1) Parkes and Wollowicz. Experiments on the Effect of Alcohol (Ethyl Alcohol) on the Human Body. Proc. Roy. Soc., 1870, xviii, 362. (No unquestionable reduction from 1-8 oz. of rectified spirits daily, or from 1-2 bottle of fine brandy in divided doses. A slight rise of 0.5° F., is complicated by the presence of a "febrile catarrh.")

(2) Parkes and Wollowicz. Experiments on the action of Red Bordeaux Wine (Claret) on the Human Body. Proc. Roy. Soc., 1871, xix, 73. (Practically no effect from 10, or from 20 oz. of good claret; certainly no rise of temperature.)

(3) Parkes. Further Experiments on the Effect of Alcohol and Exercise on the Elimination of Nitrogen and on the Pulse and Temperature of the Body. Proc. Roy. Soc., 1872, xx, 402. (No depression of temperature for three daily doses of brandy of 4 oz. each.)

(4) Parkes. On the Influence of Brandy on the Bodily Temperature, the Pulse, and the Respirations of Healthy Men. Proc. Roy.

with the views I have noted from Binz. Parkes seems to have found that the small reductions of the temperture are brought about by smaller doses, while the body is at rest and especially while fasting, than with food and exercise. In general, his men (soldiers) required rather large doses to affect the temperature, but they were all accustomed to alcohol. Or is it possible, as an eminent physiologist once suggested privately to me, that the temperature of the body has a somewhat different regulation in England from that on the Continent?

The reduction of fever temperatures by the use of alcohol has been equally fully demonstrated, and is generally admitted, so that alcohol is also considered by many that have seen this effect, to be a very important antipyretic. It would, however, lead much too far, were we to examine this aspect of the question, and I only wish to consider the physiology of the subject.

We come now to the consideration of an effect where the experimental evidence is in a very unsatisfactory condition — that on the heart. It is a fact often enough observed clinically that a weak heart can be quickened and strengthened by alcohol administered either hypodermically or through the intestinal tract. It is, however, somewhat uncertain whether we have to do here with a direct action on the heart or with a reflex stimulation.[25] On the other hand there is some evidence that such an effect is altogether problematical. Zimmerberg's dissertation (written at the suggestion of Schmiedeberg in 1869) is commonly given as authority for the statement, the stimulating influence on the heart does not exist. It has however, been urged the Zimmerberg's doses were toxic.[26]

Martin, too, in an article which I shall quote presently, seems to have found that a small dose of alcohol well diluted (15 cc. in 50 of water) does not quicken the heart-beat of a teetotaler.

The direct action of alcohol on the mammalian heart has only recently been studied, in fact the Baltimore method of isolating the dog's heart so as to permit such investigations is itself quite new. By ingeniously picking out what he wanted, Dr. Davis derives great comfort from the work of Martin and Stevens.[27] These investigators found that defibrinated blood fed directly to the heart (only the heart and lungs being in the circulation in this method of working) and containing 1-2 per cent. by volume of ethyl alcohol, invariably caused a very rapid and marked diminution in the work done by the heart in a given time as indicated by the amount of blood pumped out. With blood containing 1-4 per cent. alcohol the effect is in most cases the same, but sometimes little or none, and no influence is exerted by blood with but 1-8 per cent. at least for several minutes. This effect is due to a distension of the heart, the systole growing less and less complete. Martin calculates the amount of alcohol which would be 1-4 per cent. of the blood of an adult man and calls it about 15 ccm., or the equivalent of a good "glass" of brandy. Thus far Dr. Davis quotes him correctly in his lecture, but appears to have overlooked the following very important passage with which Martin's article in the *Maryland Medical Journal* ends (p. 294):

"We have made a few experiments to see what dose of alcohol given by the stomach to a dog will produce some similar action on the heart. When the heart lies in the body and in connection with the central nervous system there are of course considerable difficulties to be overcome, and all we can say as yet is that to get any distinct influence on blood-pressure one must put much more alcohol into the stomach than an amount equal to 1-4 per cent. of the total blood of the animal. It is either not absorbed fast enough to reach at any moment the heart-poisoning limit, or, more probably, is picked up by other organs, very likely the liver, and held back from the heart.

"We then tried in another way, by directly injecting into the jugular vein of a curarized dog, a small quantity of salt solution containing an amount of alcohol equal to 1-4 per cent. of the total blood of the animal reckoned as 1-13 of the weight. In such cases we found usually a very temporary enfeeblement of the heart, indicated by a lower arterial pressure, but this seems only to last while the injected solution is flowing through the organ, or for a few seconds afterwards. Before the blood returns it has apparently deposited its alcohol elsewhere in the body, or at any rate got rid of it somehow, so that it no longer acts immediately upon the heart, at least to a directly noticeable extent."

It will thus be seen that although the results of Martin and Stevens are probably true for alcoholized blood circulating through the heart, the body does not permit the heart to be reached ordinarily by any such amount of alcohol. The reader will see in this fresh evidence that the body disposes of the alcohol by some other process than excretion. This behavior of alcohol need not particularly astonish us, for we know now that various products of the digestive process ("peptones" or diffusible bodies standing near these), which in all probability are readily taken up from the intestine, cause much disturbance when injected directly into the blood. There is, however, some experimental evidence that alcohol really stimulates the heart and raises the blood-pressure.[28] The investigations of Parkes and Wollowicz, and those of Parkes alone, certainly show a considerable quickening of the

Soc., 1874, xxii, 172. (The Temperature of a man remaining quietly in bed was not especially changed by brandy (1 to 6), taken four hours after breakfast. During complete inanition (no food from 6 P. M., until 1 P. M., 6 ozs. of brandy being taken at 10 A. M.), the temperature was more distinctly lowered, but the average for the three hours is only 0.6° F.)

[25] Bleuler and Lehmann have recently shown (Archiv. f. Hygiene III. 215) that the pulse is readily quickened by all substances (hot water, salt solutions, etc.) which cause any feeling of burning, pressure or nausea in the stomach, or a fulness in the intestines, especially in the rectum.

[26] Zimmerberg, Untersuchungen über den Einfluss des Alcohols auf die Thätigkeit des Herzens. Dorpat, 1869. An examination of this dissertation certainly does show very large doses for frogs, rabbits, and cats, but it cannot be urged that those given the men were unduly large. The average pulse, as I figure it from the data printed, really shows less increase from alcohol than we should expect from clinical and other experience, and the blood-pressure (cats) is undoubtedly lowered in a way which does not agree with the results of other observers. The rabbits showed a very marked rise of the pulse-rate, and Zimmerberg endeavors to explain this by an experiment with the injection of water (into the stomach) which was also followed by increased heart activity. But the water effect only lasts forty minutes, while the alcohol quickening still continued at the end of the experiments, or some sixty-five minutes after taking the alcohol. Of all the animals used for this work the rabbit is the most likely to have had a considerable quantity of food in the stomach. It is, therefore, a plausible explanation that the slowness of the absorption and the continuance of a mild reflex stimulus may have raised the pulse, and it is also noticeable that the dogs, which apparently received more moderate doses do show some quickening of the pulse shortly after the alcohol was given.

[27] Martin. The direct action of ethyl alcohol upon the heart. From the Transactions of the Med. and Chir. Fac. of Maryland, 1883. In Maryland Medical Journal, September 8, 1883, p. 289. Experimental details of these experiments are given in the "Studies from the Biological Laboratory," of Johns Hopkins University, Vol. II, p. 477.

[28] See Dogiel in Pflüger's Archiv viii. 605, (unfortunately only a résumé) and the *Referat* on the (Strassburg) dissertation of Rioechiro Maki in the Centralblatt f. klin. Medicin, 1884, 685. The latter's experiments appear to have been made on the frog's heart with Williams' apparatus, and are in a measure opposed to the conclusions which Davis draws rather loosely, as usual, from the work of Ringer and Sainsbury. (Practitioner, 1883, xxx, p. 339.)

pulse in the soldiers they experimented on. This quickening seems to last too long to be merely the result of intestinal stimulation. Their sphygmograms will apparently bear the interpretation that the tension is increased, but all sphygmographic work is more or less enigmatical.

Here belong, too, the apparently careful experiments of Castillo,[29] who found (for rabbits and dogs) that small doses of alcohol accelerate the pulse by direct stimulation of the heart (the nerves being cut) with an increase of the cardiac force and a higher arterial pressure, while larger doses accelerate the pulse but diminish cardiac force and lower the arterial pressure. With an excessive dose the pulse-rate is diminished from the first; there is a direct paralysis of the heart, which always comes to a standstill in diastole. This shows, what is also generally admitted, that there is a period of the alcohol effect, often easily and rapidly reached (it being probably rather a question of quantity rather than of time), when the heart is weakened, the bloodvessels much relaxed and the blood-pressure greatly lowered. This is probably a nervous phenomenon and due to a paralysis of vasomotor centres, for Kobert found that bloodvessels showed no special change when alcoholized blood circulated through them.[30]

(To be continued.)

THE SURGERY OF THE ABDOMEN ILLUSTRATED BY EIGHT CASES.

BY D. W. CHEEVER, M.D.,
Professor of Surgery, Harvard Medical School; Visiting Surgeon, Boston City Hospital.

CASE I. PERICŒCAL ABSCESS.[1]

THE patient was a girl of ten years, who, though always delicate, had never up to the present illness, had any serious disease. For about six weeks before she was seen by me in consultation, she had suffered from abdominal pain with occasional vomiting, and feverishness. On examination there was found to be a solidification of a large part of the right lung which interfered seriously with respiration. Indistinct fluctuation was made out in the right iliac region and by aspiration at a point midway between the umbilicus and the crest of the ilium, about sixteen ounces of pus was drawn out. As at this time the child was much exhausted and the removal of the pus afforded relief, it was thought wiser to pause here. The abscess, however, refilled, and eighteen days after, the aspiration was laid open.

It was found necessary to make the abdominal incisions, one in the median line, and one at each side of it. A large quantity of foul pus was let out. The finger introduced through the median incision entered at once a large abscess cavity, extending across the abdomen from side to side, which must have held at least a pint and a half of pus. No connection with the viscera was detected, and the intestines were apparently walled off by inflammatory exudation. The cavity was washed out with carbolic solution, large drainage-tubes were inserted into the two lateral incisions and a braid of silk into the median one. Carbolized oil dressings were used. After the operation there were no signs of collapse, and the temperature fell rapidly to normal. The cavity was daily washed out with a solution of corrosive sublimate. The patient began to gain flesh and strength, and three weeks after the operation the middle sinus closed, the silk having been removed in the mean time.

Six weeks after the operation the sinus on the right side had closed permanently. That on the left nearly healed up, but began finally to discharge fæcal matter. Two months after the operation this fæcal fistula healed spontaneously.

The right lung did not entirely clear up, until about four months after the operation, at which time the child was well and strong.

The final formation of a fæcal fistula seemed to indicate some low or tubercular ulceration of the bowel. The original site of the abscess was near the cœcum and ascending colon. There was no stoppage of the bowels. Considering the feeble constitution of the child and the infarction of the right lung, together with the long duration of the illness, the recovery was a remarkable one. The spontaneous closure of the fæcal fistula was also remarkable, although this is often seen after hernia and strangulation.

CASE II. PERITYPHLETIC ABSCESS.

The patient was a Swede, twenty-three years old. He was undersized and poorly nourished. On account of the language it was impossible to obtain a complete history. So far as could be made out, however, the patient received a blow in the left groin about three months before he first came under my care, and for the last month or so pain had been present in the abdomen, gradually increasing in severity. This pain has been so constant and severe as to prevent sleep. The patient had lost flesh and strength and had little or no appetite. Micturition difficult and painful. The abdomen was enlarged symmetrically. The catheter drew off twenty ounces of clear urine, after which the right lower abdomen seemed somewhat more prominent than the left. The aspirating needle was inserted in the median line four inches below the umbilicus, but nothing was found. There was a fluctuating area on the left of median line, and the aspirating needle was again inserted, this time an inch below and to the left of the umbilicus. A few drops of pus were drawn out. With the needle as a guide an incision was made down to the peritoneum, but no pus was found. The finger introduced into the peritoneal cavity detected an induration below and to the right, which could be grasped between the finger of one hand within, and the other hand without. The needle was then introduced at a point two inches to the right, and three inches below the umbilicus, and considerable thick, foul pus evacuated. Using the needle as a director a free opening was made into the abscess cavity. The index finger introduced into this cavity, discovered three apparently blind pouches; one directed upwards and towards the first incision, a second passing outwards and towards the flank, and a third passing backwards. The abscess-cavity was irrigated with carbolic solution, and drainage-tubes were introduced. The first incision was carefully sutured, and sealed with the compound tincture of benzoin. A rectal examination was now made, and a fluctuating projection discovered on the

[1] This case occurred in the practice of Dr. G. E. Titcomb, of Concord, Mass.

[29] Castillo. The physiological action of alcohol on the circulation. Philadelphia Medical Times, 1880, xi, 44. This is an abstract of a prize inaugural essay, and unfortunately does not contain full details.

[30] Cf. Binz' Vorlesungen, p. 386. Kobert. Ueber die Beeinflussung der peripheren Gefässe durch pharmakologische Agentien. Arch. f. exp. Path. u. Pharm., 1886, xxii, 77.

anterior wall. It was apparently of about the size of an orange, and the tissues about it were indurated. Into this swelling a long curved trochar was introduced, and several ounces of very thick, extremely offensive pus were evacuated. The canula was tied in, but removed on the next day.

After the operation the patient steadily gained flesh and strength, the wounds healed rapidly, and indurated swellings in the abdomen and rectum gradually disappeared.

This was probably a case of perityphlitic abscess finally descending into the pelvis. The points of interest were the false start made by cutting down upon the needle, and the opening of the peritoneal cavity without subsequent infection.

CASE III. PYONEPHROSIS.

The patient was a woman, twenty-five years old. About two months previously she had been delivered of her first child, after a tedious labor, in which forceps were used. She had made a good recovery, and was up on the tenth day. By the end of the third week, she began to have pains in the abdomen and back, which gradually became more severe and more constant. The urine contained much sediment, mostly pus. On questioning, it was found out that the urine had been cloudy ever since the confinement. On examination of the abdomen, a tumor was found in the right lumbar region, which extended far back toward the spine, and under the false ribs. It reached, in front, to within one inch of the umbilicus. This tumor was dull on percussion, and was quite hard, though indistinct, deep-seated fluctuation could be made out. There was considerable tenderness.

An aspirating needle was introduced a little in front of the middle of the tumor, and fœtid pus was found. The needle was left in position, and an incision four inches long made from the lowest rib to the middle point of the iliac crest, in a direction downwards and slightly forwards. The anterior border of the quadratus lumborum muscle was seen running diagonally across the line of incision. The transversalis fascia was then divided, and the sac-wall disclosed. On tearing through the latter, six or eight ounces of very foul pus was let out, and the tumor disappeared. The peritoneum was not disturbed. The examining finger could make out a sinus, extending upwards toward the kidney. The cavity was irrigated with carbolic solution, and drainage-tubes inserted. They penetrated fully four inches.

After the operation the patient rallied, and soon began to gain in strength. The discharge from the tubes diminished gradually, but the sediment in the urine, though somewhat less than formerly, contained a large amount of pus. Sixteen days after the operation, a slight amount of urine escaped from the wound in the side. The cavity was, however, contracting, and the tube was introduced with difficulty. From this time on there was a gradual improvement in the condition of the patient, in spite of many set-backs. When she was last seen, some months after the operation, there was a small sinus, which discharged slightly from time to time. A round swelling, about the size of an orange, was still to be felt in the right side. The urine contained a faint trace of albumen and considerable sediment, mostly pus.

It was quite uncertain, in this case, whether the disease was puerperal or not. Life was saved by bold operative procedure, but the entire disease was not yet removed. To remove the suppurating kidney, was a question for future consideration. It seemed probable that this was a perinephritic abscess, opening early into the pelvis of the kidney.

CASE IV. PELVIC ABSCESS.

The patient was a single woman, thirty-one years old. She had never had any children. Was well up to within four years, at which time she had "inflammation of the bowels." She recovered from this illness, and was able to return to work. Within the last six months or so, she had suffered from a stopping of the catamenia, with pains in abdomen and back. The pain in the abdomen had been, for the last two weeks, severe enough to prevent sleep. The patient had been losing flesh and strength; constipation was present, as well as a frequent desire to micturate; urine cloudy when passed, and contained large amount of pus.

On palpating the abdomen, a large mass, painful on pressure, was found occupying the lower part of the abdomen, on the left side. It was apparently above the true pelvis. No fluctuation could be made out, and the aspirating needle, thrust into the most prominent part of the mass, failed to discover pus. A careful vaginal examination, with the sound in the bladder, gave no additional information as to the limits and position of the tumor. The urethra was then dilated, and the index finger introduced into the bladder. This viscus seemed to be attached high up, but no opening into it could be made out.

The bladder was washed out daily with antiseptic solutions, and the patient gained in strength, and the pain decreased, though the urine still contained a large amount of pus. Suddenly, pus began to be noticed in the stools, showing that an opening had been made into the rectum. Eventually, the patient made a perfect recovery.

The refraining, in this case, from opening the peritoneal cavity, when a vent for the abscess existed through the bladder, was rewarded by entire recovery through the outlets made by nature. It is a well-known fact that pelvic abscesses are much more likely to recover spontaneously than those wholly within the abdomen.

CASE V. INTESTINAL OBSTRUCTION FROM VOLVULUS; ABDOMINAL SECTION; ARTIFICIAL ANUS; DEATH.

(This case occurred at the City Hospital, in the practice of Dr. G. H. Lyman, who transferred it to me for operation.)

A well-developed young man of twenty-three years, who had, up to the present illness, always been well, was seized with abdominal pain and tenderness, particularly in the region of the umbilicus. There was persistent constipation and vomiting. The vomitus, at first thin and colorless, later became stercoraceous. Warm-water enemata, introduced through the rectal tube, failed to bring away more than a few small fæcal lumps.

The patient's condition growing gradually worse, and collapse threatening, he was transferred for operation.

An incision five inches long was made in the right linea semilunaris, downwards from the level of the umbilicus. The bowel was moderately distended and dark-colored. The cœcum could not be found. The hand, passed into the peritoneal cavity, failed to detect

any adhesion, hernia, or twist. The small intestine was opened and stitched to the lower extremity of the abdominal wound. About seventy-two ounces of thin, fæcal matter was discharged. The patient could not be made to rally, but died quietly three hours after the operation.

An autopsy was made by Dr. Gannett, fifteen hours after death. On opening the abdominal cavity, a portion of the large intestine, enlarged to about the size of the calf of a man's leg, was found lying diagonally across the abdominal cavity, from the right ileo-cœcal to the left hypochondriac region. The cœcum was a portion of this, and occupied the last-named position. The upper 30 cm. of the large intestine, and the lower 150 cm. of the small one, were markedly distended, injected, and in patches showing a uniform, dark-bluish appearance.

The portion of large intestine below the distended part mentioned was of about the size of the thumb. It was found that the *cœcum had no attachments*, and that the ascending colon had a long meso-colon, and that this portion of intestine had been twisted once-and-a-half on itself, in the direction of the hands of a clock. This caused a constriction at a point 30 cm. below the ileo-cœcal valve, through which, evidently, nothing could pass. A revolution and a half of this portion of large intestine restored it to its normal position.

The opening in the small intestine, which corresponded to the external wound, was situated 300 cm. above the ileo-cœcal valve. The constricted portion was very dark in color, but showed no evidence of actual necrosis.

The autopsy revealed the reason why the cœcum could not be found *in situ*. Although all the symptoms pointed to the right side of the abdomen, and the incision in the right linea semilunaris was over this, yet it would have been better had a long median incision been made. The operation should have also been undertaken earlier.

CASE VI. STRANGULATED INGUINAL HERNIA; HERNIOTOMY; RESECTION OF INTESTINE; DEATH.

The patient, a well-built, hardy-looking sailor of twenty years, had had a reducible hernia for years, but had never worn a truss. He thought that he strained himself while at work on his vessel, for there was a pain in the region of the hernia, and that night the rupture would not go back as usual. All the symptoms of strangulation set in, but it was not until four days afterwards that his vessel reached Boston, and he was taken to the City Hospital. There was found in the right groin, extending from the external ring to the lower extremity of the right side of the scrotum, a prominent swelling of a red, dusky hue, the size of a fist. The overlying tissues were œdematous and somewhat tender. Abdomen moderately distended and tender.

A vertical incision was made over the most prominent part of the tumor, and passing nearly to the end of the scrotum. The tissues were divided, layer by layer, until the sac was reached. This was punctured, and several drachms of a dark-colored fluid escaped. In the sac was a portion of omentum, almost black, lying in contact with the testis (the hernia being of the congenital variety).

Under the omentum was a loop of bowel, apparently almost necrotic. There were adhesions at the rings. After free incision of the constricted parts, *including both rings*, healthy bowel was brought down, and resection decided upon. The incision was carried up in the right linea semilunaris for three inches. The necrotic omentum was excised, and the stump secured in two sections by carbolized silk and dropped into the peritoneal cavity. The dark portion of the intestine was removed, together with a good margin of apparently sound gut on each side. The mesentery was secured by a running suture. The ends of the intestine were united by a dozen Lembert stitches, and the whole was then dropped back into the abdominal cavity and the wound closed.

The patient rallied quite well from the operation, but persistent vomiting set in, and finally, collapse, and the patient died quietly eighty-four hours after the operation.

The post-mortem examination showed that the bowel was turned sharply on itself at a point one foot above the cœcum, the finger thus formed being thrust down into the right side of the pelvis, and so firmly fixed there as to require considerable force to dislodge it. The neck of this loop was so constricted that no fæcal contents, evidently, could pass. The intestine above was much distended with gas and fæces, while all below was empty. The point where the bowel had been sutured was found three inches *above* the sharp turn in the bowel, the bowel being collapsed between the two points, and bluish-black at the constricted point.

At the point of suture the intestines were all adherent in a mass, and were so fastened to the abdominal wall that a portion of the latter had to be removed in getting them out. The intestine above was covered with injected vessels — that in the vicinity of the wound was covered with masses of fibrinous false membrane. Union was very perfect, apparently, lymph having filled up the sulcus between the two rolled-in edges, except at one point, where these edges seemed to have sloughed off, and at this point a probe could be passed out into a cavity which had been walled off by peritoneal adhesions. Along the mesenteric border, when the surrounding intestines, which were closely adherent, were pulled away, was found a small quantity of pus.

This patient died of combined external strangulation at the ring (hernia), and internal strangulation within the pelvis.

Probably the strangulated hernia preceded the other condition. Strangulated hernia of five days' duration commonly ends in death, or artificial anus. The necrosed piece of intestine removed was from three to four inches long; the gut on either side appeared well, and the internal strangulation, lower down, was not discovered. The sloughing condition of the scrotum was also an element in the prognosis. The patient was a tough young sailor, and survived his first attack eight and a half days.

CASES VII AND VIII.[2] STOPPAGE OF BOWELS. RECOVERY WITHOUT OPERATION. STOPPAGE OF BOWELS WITH PERITONEAL IRRITATION.

The two following cases occurred in the practice of Dr. George B. Shattuck, and he has kindly allowed me to report them.

C., a cabinet-maker, fifty-four years of age, entered the Boston City Hospital, October 9, 1886. Accord-

[2] See page 13 of the Journal.

ing to his account six or eight months previously began to have pain in the umbilical region, frequent eructations, a good deal of nausea, and occasional vomiting; had some shortness of breath and general weakness, but continued to work up to four days before coming to the hospital; since which time his bowels had not been moved; he had had great pain all over the abdomen, so severe as to keep him awake at night and prevent his lying on his back or straightening out his thighs; had kept his bed for the past four days, vomiting all food and the medicines he had taken, among which were cathartics.

On admission, temperature 99.6, pulse 88, respiration 36; tongue covered with thin white fur; abdomen somewhat distended, tympanitic, very sensitive throughout to deep pressure. Was ordered twenty minims of the deodorized tincture of opium, to be repeated in an hour, *si opus sit.*

October 10th. Fairly comfortable night, less pain, bowels moved slightly by enema. Liquid diet, small quantities frequently repeated. Opium continued, *pro re nata.*

October 11th. Vomited several times during the morning, the vomitus being stercoraceous. Pain controlled by opium. A rectal injection of five pints of tepid water administered with long rectal tube brought away very little fæcal matter.

October 12th. Abdomen less tympanitic, softer, less tenderness, no vomiting; some prominence in the umbilical region; patient takes scarcely any nourishment; vomited several times, vomitus stercoraceous. Large enemata of tepid water without result.

October 13th. Occasional vomiting of same character, rather more tenderness and fulness at the umbilical region. Enemata without result. Temperature 98°, pulse 88. (Seen by Dr. Cheever with reference to the propriety of surgical interference.) "This I decided against because I could not localize the difficulty. The patient looked badly, haggard, anxious, and emaciated; vomiting and tympanites were the prominent symptoms — but it did not seem to me that an incision afforded sufficient promise of success."

October 15th. Enemata continued since last record, and on this day a good deal of thin fæcal material came away. No vomiting since the 13th, patient somewhat more comfortable with a little relish and desire for food.

October 16th. Bowels moved spontaneously, a moderate amount of thin, orange-yellow fæcal material being evacuated. Temperature normal, pulse 80.

October 19th. Enemata continued, and much thin fæcal matter has been evacuated during the last few days. Last night, after several hours of severe pain, patient passed per anum, a hard irregularly cylindrical mass with rounded ends, measuring three-and three-fourths inches in length, and one-and-one-fourth to one and one-half in diameter, so hard as to be broken with difficulty, of slight fecal odor, consisting of dark orange and grayish material in flakes and lumps, firmly compacted together.

A. B., female, forty-three years of age, single, domestic service. Always had had very good health. Entered the City Hospital October 27, 1886. Three months before began to have diarrhœa, dejections watery in character, at times very frequent as often as every hour, followed by pain in bowels and back-passage. Occasional vomiting for several weeks and some incontinence of urine, both of these symptoms absent for two weeks before coming to hospital, and the diarrhœa less frequent. Had lost much flesh.

On admission complained of some pain in lower abdomen and small of back.

Examination showed that the abdomen was considerably distended and tympanitic, with marked tenderness and sense of resistance in the right iliac fossa. Rather frequent diarrhœal dejections.

November 2d. No movement of bowels since October 28th. Examination by rectum found the rectum filled with masses of soft putty-like fæces. A hard body felt on the right side, pushing in the wall of the rectum. Attempts to empty rectum by enemata were fruitless. Taking very little nourishment. Vomiting at times, and complaining of rather severe abdominal pain.

November 4th. Vomited frequently, abdominal distension, pain and tenderness increased; tenderness general, but most marked as before, in the right iliac region. Pulse small, increased weakness. Seen in consultation by Dr. Cheever who considered surgical interference undesirable, and thought the chronic peritonitis was possibly due to malignant disease. In this case the aspect was sunken and almost that of threatening collapse.

November 7th. Less pain. less vomiting, increased desire for nourishment. Rectum emptied, and examination by Dr. Cheever who found a hard lobulated tumor behind and at right side pushing in the rectal wall.

November 8th. Enemata of castor oil and olive oil administered since yesterday, had brought away several masses of hard fæces, and during the night the patient had four spontaneous movements, the first since October 28th.

January. The patient is still in the hospital, and a tumor is now very evident above the pubes. She suffers from paralysis of the rectum.

PROGRESS IN DENTISTRY.

BY WILLIAM HERBERT ROLLINS.

EFFECTS OF URIC ACID ON THE TEETH.[1]

The effects of uric acid in the blood is an absorption of the alveoli of the teeth, or this absorption may be accompanied by a new deposit of bone. In some cases, the processes occur side by side on the same alveolus, as on the superior molars, where it is not uncommon to find on the palatine roots absorption, both of the gums and alveoli, while, on the labial roots, the thickness of the alveolus is increased. The formation of tophus often accompanies this disease of the teeth. When it is present, absorption of the alveoli always precedes the deposit by about a sixteenth-of-an-inch. Not infrequently, the uric acid tophus is mixed with a deposit of phosphate of lime. The uric acid dissolves the pericemental membrane. This solution may be free from pain, but usually there is a sense of uncomfortableness in the teeth which are attacked. In addition to the usual constitutional treatment, alkalies should be applied to the gums, as they have the power to dissolve the deposits. Carbonate of soda is mixed with chalk and some pleasant essential oil, and the patient is directed to rub the mixture on the gums before going to bed.

[1] Reese in Independent Practitioner, p. 247, 1886.

CHANGES IN THE TEETH IN LOCOMOTOR ATAXIA.[2]

The writer believes that the changes which are found in the trigeminal nerves, and the functional disorders that may result from them, favor the growth of germs, which, in his opinion, are the immediate cause of the loss of the teeth. He was not able to find any differences in the teeth lost in this disease from those shed in the ordinary alveolar pericementitis.

A NEW STREPTOCOCCUS.[3]

Mr. Black describes a new streptococcus, which he considers the cause of sordes in fevers. Cultivated on gelatine, its colonies become milk-white in three hours, and in tubes of peptonized broth, the contents are completely gelatinized in fifteen hours. Unlike other streptococci, it does not form in pairs or rows of even numbers, odd numbers being as frequent. When present, the dorsum of the tongue is its favorite seat.

FOUR SETS OF TEETH BEFORE THE AGE OF FIFTEEN YEARS.[4]

The child, who was under the care of Dr. Gatching, developed the first set of teeth at the age of six months. These teeth were all shed at nine months. At eleven months, she began teething again, another set of teeth being erupted in four months. Six weeks after, these teeth began to crumble, and were entirely lost. Her weight at this time was ten pounds. At thirty months the third set appeared, and these remained till the age of four years, when they were extracted. The fourth set began to erupt at eleven years, and the dentition was complete at fifteen.

SYPHILIS IN RELATION TO DENTISTRY.[5]

The patient who intends to go through a course of treatment for syphilis with a minimum of suffering must place himself in the hands of a competent dentist, because tartar, carious cavities, or any rough points about the teeth are almost sure to produce a most luxuriant growth of mucous patches or destructive ulcerations. When the teeth or gums are out of order, the patient is so intolerant of mercury that it is almost impossible to give him enough for his disease. These oral lesions are so actively contagious, that every precaution should be taken to clean the instruments after they have been used. A lesion so slight as to escape notice, may be the means of transmitting the disease to another person through improperly cleaned instruments. A safe rule is to use no instruments which we should hesitate to put in our own mouths. Lydston does not consider that the absence of Hutchinson teeth invalidates a diagnosis founded on other grounds, and points out that few children so badly affected reach the age of teething.

RELATIONS BETWEEN DISEASES OF THE GUMS AND DISEASES ELSEWHERE.[6]

The various skin eruptions, vomiting, convulsions, diarrhœa, and constipation, so frequently found to be coincident with teething, are supposed by the writer to be due to an infection of micro-parasites in the gums. For treatment, he uses a mixture of chloride of sodium, two parts; iodine, one part; and water, two hundred parts. With the paling of the gums which follows the local application of this mixture, there is a concomitant subsidence of the catarrh of the respiratory and digestive surfaces, and the feverishness and reflex nervous phenomena come to an end.

ACCIDENTS IN TOOTH EXTRACTION.[7]

The patient was supposed to have a malignant tumor of the rectum, for a hard, well-defined tumor, painful to the touch and ulcerated, could be felt encroaching on the external sphincter. She was put under preparatory treatment for an operation, but, being attacked by pneumonia, the operation was delayed, and in the course of a few weeks, while at stool, a hard point was felt in the tumor, which, on removal with the finger, proved to be a tooth. She then remembered that, fifteen years before, she had swallowed a tooth when her teeth were being removed for an artificial set.

GASTROTOMY FOR THE REMOVAL OF ARTIFICIAL TEETH.[8]

The patient, a robust man, thirty-seven years old, swallowed his teeth September 23d. By July 23d he had lost sixty-seven pounds, and was growing weaker. Therefore, an operation was decided on. A preliminary examination showed that the plate was in the œsophagus, fourteen inches from the incisor teeth. On August 5th, an incision six inches long was made, one-and-one-half inches below, and parallel to, the margin of the left hypochondrium. It began at the outer border of the rectus abdominis, and three inches from the tip of the ensiform cartilage, extending outwards and downwards. The stomach was drawn out and placed on a carbolized towel. An incision large enough to admit the hand and forearm was made in its walls. The middle and index fingers being inserted into the œsophagus, grasped the plate and removed it. The patient recovered rapidly, weighing, on November 13, forty-six pounds more than at the time of the operation.

GANGRENE OF RIGHT LUNG FOLLOWING PYORRHŒA OF THE TOOTH-SOCKETS.[9]

The patient, thirty-one years old, was far from strong, and for many years had suffered from Rigg's disease, from which her teeth were so loose that they were extracted. Under the anæsthetic given for the removal of the teeth she collapsed, rallying under stimulants. The gums healed rapidly, in three days showing no signs of suppuration. For a day or two the patient seemed to be recovering, but on the fifth day the temperature rose to 103.4°. Then followed cough, scanty expectoration of viscid sputa, which grew more putrid. Death took place on the nineteenth day. The autopsy showed many cavities in the right lung, filled with foul, greenish-yellow fluid.

LOSS OF SIGHT FROM AN ULCERATED TOOTH.[10]

An unsuccessful attempt was made to extract an upper eye-tooth. Great swelling of the face followed, an abscess forming in the orbit, which resulted in total loss of sight. An examination, two months afterward, showed the disk white and sharply outlined. From its lower edge, there ran three white lines downward, the remains of the obliterated vessels.

[10] Burnett in Ohio State Journal of Dental Science, p. 331, 1886.

From the upper edge, ran one white line, and a narrowed artery and vein still containing blood. The fundus was even in tint, with two exceptions: pigment patches were found in the macula region, interspersed with white lines. The interest of the case lies in the similarity of the ophthalmoscopic appearances to those seen in blindness after facial erysipelas.

EXCISION OF THE LOWER JAW FOR THE RELIEF OF MECHANICAL TRISMUS.[11]

He reports three successful cases, and recommends the operation in all similar ones. The directions given for operating are to take the tragus of the ear as a guide, and make a horizontal incision of an inch across and down to the neck of the jaw, so as to divide the neck by means of strong cutting-forceps, and then to evulse the condyle by impacting a strong steel point into the bone, to act as a lever to turn out the bone. The interarticular cartilage is left, to prevent osseous union. This operation is another instance of the warrantable sacrifice of healthy parts so as to affect the well-being of the whole body.

CYSTS OF THE JAW.[12]

There are two kinds of cysts in the jaws. The first are due to tooth-germs which have not developed. The second arise from the periosteum surrounding the roots of the teeth. Under some inflammation the periosteum separates from the tooth and forms the wall of the cyst. The fact of the second kind of cysts being sometimes lined with epithelium does not prove that these cysts are formed from masses of epithelium left over in the jaws from the days of tooth formation, as it may easily rise from the original follicular membrane which surrounds the tooth-germ and which is afterwards converted into the root-membrane in the adult tooth. Each cyst that has its starting point at the root of a tooth, results from a previous lesion of that organ, and is immediately dependent on the inflammatory exudation which arises in the ligamentous fibres surrounding the root, which remains free and denuded in the sac. This mode of origin is similar to that of sub-periosteal abscesses, the difference being that owing to the intensity of the inflammation the exudation is purulent, while in the other it is serous. The treatment of the second form of cysts consists in inserting minute metal drainage-tubes through which suitable antiseptic and astringent washes are to be injected. Magitot claims to have used this treatment with success for ten years.

PLANTING TEETH IN ARTIFICIAL SOCKETS.

Dr. Younger has invented this new operation. When a tooth has been lost he drills a suitable hole in the alveolus. Into this hole, which should be of the same shape as the root of the tooth to be planted, he forces the tooth which has been previously filled and soaked in a solution of bichloride of mercury in water, of a strength of one to a thousand. In most cases no ligatures are required to hold the tooth in position. There is little soreness of the parts, and in a day or two the tooth feels like the others in the mouth. Younger considers a tooth which has been out of the mouth for several years as good as a recently extracted one, as the root-membrane retains its vitality as do seeds. There are two dangers in the operation; First, one may transmit syphilis or other disease; Second, the planted tooth has no living pulp and is more liable to decay, and like all pulpless teeth may ulcerate. I have examined the teeth of sheep with the view of dissecting out the incisors of a freshly killed animal of the proper age to have the roots unclosed. The pulps in these cases are large, and if properly cut off and inserted into the human jaw ought to go on growing. If this should happen, the roots would close and the tooth would then be a living tooth, instead of a pulpless one. By cutting off the ends of the crowns of a sheep's incisors, these would answer very well for this purpose, and if Younger's operation is really a successful one as tried by three or four year's time, this experiment will be made.

ON THE IMPORTANCE OF REGULARLY EXAMINING THE SALIVA.[13]

Now that we know that decay in the teeth is due to acids formed from fermenting substances, the importance of keeping the saliva alkaline cannot be overestimated. If it is acid or neutral, it cannot neutralize the acids formed in fermentation, which collecting in the spaces between the teeth and about their necks, are certain to produce decay. The patient should be taught the use of litmus paper, and directed to test the reaction of the mucous membrane and parotid saliva at least once a week. If the reaction is acid, he should take the remedies found appropriate to his case. Fermentation takes place in every mouth, and yet there are many persons in whose mouth decay is either wanting or is what may be called accidental. In all such mouths the reaction of the saliva is always alkaline.

ADMINISTRATION OF NITROUS OXIDE.[14]

As at present given, the gas is exhaled into the surrounding air through a separate valve. The patient in this way always inhales the pure gas. Hewett claims that anæsthesia can be made longer by inhaling the fresh gas till anæsthesia has begun; then by turning the stopcock, shutting off the supply of fresh gas, and allowing the patient to breathe in and out of a bag of gas holding two gallons. He gives the following explanation of the method. If, after allowing the patient to breathe fresh gas till anæsthesia has begun, we then present to the lungs and so to the cerebral centres, an atmosphere of nitrous oxide, which is not quite so concentrated, in other words, one which contains a little oxygen, the respiratory centres will continue to discharge rythmic impulses, and so respiration will go on longer than it would were fresh gas constantly inhaled. In this way the whole of the blood becomes saturated, and so the anæsthesia is prolonged.

EFFECTS OF TINCTURE OF CHLORIDE OF IRON ON THE TEETH.[15]

A tooth immersed in a solution of the tincture in eight parts of water has its enamel entirely destroyed in one hour. The tincture, therefore, should never be diluted with water before it is taken, as this dilution makes the preparation more active than the undiluted tincture, for the hydrated oxide of iron which is thus formed, does not adhere to the teeth as strongly as the anhydrous peroxide that forms in the original preparation, and on this account they are

acted on more rapidly. For administration, the preparation should always be diluted with alcohol or syrup.

TREATMENT OF SALIVATION IN PREGNANCY.[16]

The author considers that his experiments, which are extensive, show that bromide of potassium is the most efficient preparation for this purpose. In one of his analyses of saliva, he found that ptyalin was entirely absent.

ON THE ABSORPTION OF DENTINE.[17]

The experiments were undertaken to determine whether the structures of the teeth took any part in the absorption of their roots, or whether this absorption was due entirely to cell-formations of the root-membrane or other tissues outside of the tooth. In order to prevent the participation of the teeth in the process, it was decided to see if the same absorption would take place out of the mouth. Pieces of tooth were introduced into the abdomen by means of incisions through the skin and deeper tissues. After periods varying from three weeks to three months, the rabbits were killed and the pieces examined. They were in every case found encapsulated with connective tissue densely filled with round cells. On decalcifying and making sections, the dentine separated from the surrounding capsule, leaving a hole exactly like the piece of tooth. In the pieces examined after six weeks, the process of absorption had begun at all points not covered with pericementum. At these latter points a perfectly firm union had taken place with the surrounding tissue, so that the dentine could not be removed without tearing the new membrane. In no case was there union except when the cementum was present. Taken in connection with the contribution of Younger on the vitality of the periosteum of the root, Miller's investigations show how important it must be in performing Younger's operation of tooth-planting, to preserve the cementum of the root unimpaired, as even when the periosteum is torn off the soft tissues of the cementum evidently have the power of producing a new covering, just as in bone, which has been deprived of its periosteum there is in favorable cases a new covering developed from the soft tissues of the bone. Cementum resembles bone so closely in some ways that this similarity might have been expected.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

G. H. MONKS, M.D., SECRETARY.

MEETING February 2, 1887. DR. J. C. WARREN, in the chair.

DR. DAVID W. CHEEVER showed a specimen of

OSTEO-SARCOMA OF THE SCAPULA

of five years duration, and related the history of the case.

The patient was a strong woman, and it was decided to operate, with a view of probably removing the scapula, and leaving the arm. It was found that a strong bony bridge united the scapula by the coracoid process to the clavicle. A portion of the outer end of the clavicle was cut away, and then the whole growth removed with the entire scapula; the arm was left. Hæmorrhage was slight, but shock extreme; and the patient survived the operation only a short time.

The statistics of removal of the entire scapula are very favorable. The mortality is about twenty per cent.

Had the growth been free and on the scapula alone the operation would have been less prolonged and probably not fatal.

The key of the operation is to unlock the coracoid process from beneath the clavicle; and at this most dangerous part of the operation, involving the vicinity of the subclavian vein and artery, and of the brachial plexus, the dissection of the subclavian triangle was impeded by the synostosis of the scapula and clavicle. The subclavian region was overlaid by a dense bony plate. It was divided and raised without injuring any large vessels or nerves. The supra-scapula, posterior-scapula, and sub-scapular arteries were controlled without difficulty.

DR. D. W. CHEEVER read some remarks upon

ABDOMINAL SURGERY: ILLUSTRATING THEM WITH EIGHT CASES.[1]

DR. M. H. RICHARDSON spoke of the difficulty of removing a kidney which had been for a long time the seat of a suppurative process. In such cases the surrounding parts become so closely adherent that it is almost impossible to isolate the kidney itself. This difficulty had been met with the past summer in making an attempt to remove a kidney which had been suppurating for many years, and from which the speaker had removed a calculus several years before. On cutting down upon the kidney nothing was found remaining of its original structure except a thin shell so closely adherent to the surrounding parts that its removal was out of the question. The original cavity of the pelvis had become enormously distended, and very little, if any, of the renal substance remained. This cavity was drained and the patient made a good recovery, with a small sinus still discharging when he left the hospital.

DR. J. C. WARREN said that the attention of surgeons had been called anew to pus in the neighborhood of the appendix vermiformis, by the interesting article of Dr. R. H. Fitz, which had recently appeared. A case which had come under his care at the hospital in December, was worth quoting in this connection. The patient, a healthy Irish woman, forty-seven years of age, the mother of three children, doing "scrubbing" for a living, presented herself at the hospital with a painful swelling in the ileo-cæcal region of one week standing. Three or four weeks previously she had an attack of acute pain at this spot which confined her in bed two days. Eight days before entrance she exposed herself to wet, and on the following evening was seized with severe pain, a chill and considerable nausea but no vomiting. The pain had continued since in the right iliac region. There was no constipation.

On examination a large indurated mass was felt in the right iliac fossa with a distinct outline extending from just below the margin of the ribs to the crest of the ileum. No induration or redness of the abdominal parietes was found. The swelling was tender all

[1] See page 6 of the Journal.

over, but very painful at a spot one-and-one-half inches above and one inch anterior to anterior superior spinous process. The expression was anxious, face flushed, tongue furred, pulse 90, nausea, but no vomiting. A poultice was applied for the relief of pain. Two days later an aspirator was introduced at the tender spot, but no pus found. Nevertheless, after consultation with Dr. Fitz, an incision was made on the following day, beginning a little in front of and below anterior superior spinous process, and extending upwards and backwards three-and-one-half inches. The various layers of the abdominal wall were divided and the surface of the swelling reached. A trocar was thrust into it in the direction of the pelvis and about three ounces of bad smelling pus evacuated, the opening was enlarged and a large drainage-tube inserted and stitched to the upper end of the wound which was closed by suture. The temperature, which was 102.5° on the evening previous, sank in two days to normal and continued so until the wound was entirely healed a month later.

DR. RICHARDSON spoke of the treatment of obstruction to the bowels sometimes seen after the operation of herniotomy has been done. In one of his cases the reduction of strangulated bowel had been followed by complete obstruction. At the end of four days the question of interference came up. The only methods of relief were in resection and artificial anus, it having been first determined that there was gangrene of the intestine. After consultation, resection of the gangrene bowel was decided upon and performed. About nine inches of gangrenous bowel were removed, and the ends of the healthy intestine brought together and sutured with silk, which had been specially prepared for a previous operation on the stomach. The patient died in twelve hours from exhaustion. The bowel was removed and found to be perfectly tight and the surfaces already firmly glued together. The operation lasted but twenty minutes, and probably added but little to the profound shock which already existed as a consequence of five days of complete obstruction and gangrene.

In this case it seemed best to do resection because the condition, which is most to be feared after this operation was already present, that is, the existence of a septic process in the peritoneal cavity. The operation of excision of the putrid mass would add nothing to the already existing local peritonitis and very little to the shock. The operation of making an artificial anus would not remove the danger of general peritonitis and would require an equally dangerous operation at some future time. It seems quite probable that this operation would have resulted favorably, considering the appearance of the specimen, had there been sufficient strength on the part of the patient to have resisted the prolonged shock of total obstruction, and gangrene.

DR. BRADFORD related a case of strangulated hernia which he had met with in practice, and in which he sewed the gut to the opening, on account of the gangrenous condition of the strangulated portion. The hernia was in the right femoral region. The patient recovered from the operation, but died in about ten days afterwards from starvation, it being found at the autopsy that the strangulation had occurred so near the pylorus that not enough of intestine remained above the artificial anus to carry on nutrition. The fact was noteworthy in that it is quite unusual for the upper part of the small intestine to occupy the region in the vicinity of the hernial canal.

DR. GEO. B. SHATTUCK thought that in the past, as formerly with tracheotomy, the tendency had been, as a rule, to delay too long the consideration of the propriety of operative interference in cases of intestinal obstruction. Not that such interference was by any means always advisable, but the advisability should be carefully weighed before collapse rendered the operation desperate if undertaken. From such motives Dr. Cheever had been asked to see the two cases reported as having been in Dr. Shattuck's service at the City Hospital. The event in each of these cases had certainly justified Dr. Cheever's decision not to resort to laparotomy. The first case had recovered completely by means of repeated large injections, and the second case had slowly gone on to a fatal termination, shown by the autopsy to be due to tuberculosis originating in the fallopian tube, followed by abscess and general chronic peritonitis.

The plug or enterolith which was brought away in the first case was of a peculiar character and had been given to Dr. Gannett for analysis, but had not yet been reported on. Its gross appearance suggested those cases of obstruction from drinking shellac, so common among the poorer classes of furniture-polishers in Berlin, where after the absorption of the alcohol, which is the temptation, the resin collects in the intestine. The patient, singularly enough, was a cabinet-maker by trade, but a respectable, intelligent man who denied having indulged in further intimacy with his shellac bottles than drawing the corks with his teeth, and who was sufficiently well off to have procured alcoholic stimulant in a more attractive form, had he desired it.

DR. DOUGLAS GRAHAM said that at a meeting of the Royal Medical and Chirurgical Society, which was reported in the *London Lancet*, December 18, 1875, Dr. Brinton stated that of six hundred cases of intestinal obstruction, fifty-three per cent. were due to intussusception, and of these thirty to forty per cent. terminated favorably. The question was asked whether such a dangerous operation as laparotomy was justifiable in this affection in which the proportion of cases of recovery by other means was so high. Dr. Brinton also stated that the operation of laparotomy is only of value in the early stage of this malady, when the condition was one of obstruction and not of enteritis.

Dr. Graham added, that massage had been used in a number of these cases after the failure of other means, laxatives, anodynes, fomentations and injections, and in all the cases *reported* this method had proved successful, recovery resulting. It may have been employed in other cases *not reported*, where it was of no benefit or possibly did harm. In such cases massage should not be employed in the presence of inflammation, enteritis, or sloughing.

DR. G. H. LYMAN spoke of the value of an early diagnosis, which could often be made in pelvic abscesses by a vaginal examination. Such abscesses should, if possible, be drained at once.

DR. E. H. BRADFORD said that most of the cases of abdominal abscess which he had met with in practice were cases of psoas abscess which had not descended to the leg, and that the patients were chiefly children. He advocated early operation, if possible, before the abscess has reached the leg. He employed

the method first recommended by Kocher, of opening the abscess in the loin, and in the groin also as soon as it pointed there.

DR. EMERSON in connection with the conservative treatment of abdominal abscesses, mentioned a case of his own, a psoas abscess, where through the neglect of the mother the child was not returned for treatment, but was kept in a plaster jacket for about a year, at the end of which the psoas abscess which formerly had pointed in the groin was not to be found. It had apparently dried up.

DR. J. W. ELLIOT mentioned three cases of his of suppurating ovarian cyst which had shown the good effects of drainage. He had followed Tait's recommendation to do laparotomy and drain from above.

THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, May 19, 1887.

DISCUSSION ON THE MANAGEMENT OF EMPYEMA, MEDICAL AND SURGICAL.

DR. L. EMMET HOLT read the first paper, his subject being:

SPONTANEOUS ABSORPTION IN EMPYEMA IN CHILDREN, AND THE RELATIVE ADVANTAGE IN CHILDREN, OF ASPIRATION AND EARLY INCISION.

More than one-half of all the cases of empyema, he said, occurred in subjects under ten years of age. The prognosis, however, was much better in children than in adults. Spontaneous absorption might possibly occur; but it was extremely rare, and he had been able to find but two cases of this on record, in which the diagnosis was verified by the test of the hypodermic syringe. As a result of his studies it was evident that the chances of recovery by means of nature's unaided efforts were very small. Having remarked that empyema was in reality nothing but an abscess in which the outer wall was rigid and the inner wall yielding, he said that the indication for treatment was to try to get rid of the pus in the easiest and safest manner possible, and that the only methods which he should discuss were aspiration and free incision.

The advantages claimed for aspiration were the following: (1) Simplicity; (2) freedom from danger; (3) that it does not remove the fluid rapidly; (4) that it does not require general anæsthesia; (5) that it does not require that the patient should be confined to bed; (6) that many cases are cured by aspiration alone. As a matter of fact its advantages, with the exception of the last, were not superior to those of incision. Of 121 cases of aspiration collected by him, 23 cases, or 19 per cent., were cured and six died. The remainder were subjected to other methods of treatment. In all but one of the 21 successful cases the empyema was localized, and in 8 a single aspiration was sufficient to effect the cure. Aspiration had many obvious objections, and among them were the following:

(1) The entire quantity of fluid cannot be removed by this means.

(2) The terror often excited in children, especially when the aspiration has to be repeated a number of times, constitutes a serious obstacle to its success.

(3) Where septa exist in the pleural cavity, but one division of the latter may be evacuated.

(4) There are certain cases where aspiration is not available, and if the case is allowed to go on for a considerable time without evacuation, septicæmia and other serious consequences are liable to result.

Among the advantages of incision were, first, its universal applicability, and, secondly, the fact that it enables the surgeon to explore the pleural cavity thoroughly. While the exposure of the cavity and the admission of air were formerly well-founded objections, since the introduction of antiseptics this was no longer the case. As to the use of general anæsthetics Dr. Holt said that he knew of two instances in which death resulted from this cause, in consequence of the rupture of a bronchus. He had never known of this untoward result occurring in a child, but he thought these cases were sufficient to warn us against the use of general anæsthetics in cases of empyema. He did not know whether local anæsthesia by cocaine, had been resorted to in this connection, but he should suppose that this would answer every purpose.

Considering the results that were met with, he thought it was no wonder that a low estimate was entertained of the operation by the older surgeons, and he quoted the opinion of Sir Astley Cooper and others, whose experience led them to regard it as almost necessarily fatal. He had collated 59 cases in children performed at a later period, but before antiseptics had come into as general use as at present, in which there were only eight deaths. Out of 63 cases in which the operation was done under strict antiseptic precautions, however, there were but two deaths: and he thought that no more complete evidence than this could be furnished as to the advantage of antiseptics. As to duration, out of 80 cases in which antiseptics were used, 5 cases lasted 4 months, or more; and in the remaining 75, the average duration was 6 weeks. In 21, the duration was one month, or less. In cases in which antiseptics were not employed, the average duration was 6 months.

DR. HOLT'S conclusions were as follows:

(1) All methods yield better results than non-interference.

(2) No case should ever be left to the unaided efforts of nature.

(3) Aspiration holds out a possible chance of cure, especially when the empyema is localized.

(4) If, after two aspirations, the fluid continues to accumulate, this method should not be persisted in.

(5) In large effusions it is well to make one aspiration before resorting to incision.

(6) In all other cases a free incision should be made, preferably under local anæsthesia.

Finally, he said, we could have no better guide, as a rule, in empyema, than Wagner's words, "Early incision, perfect drainage, and complete antisepsis."

DR. F. HUBER read a paper on

ACUTE EMPYEMA IN CHILDREN,

in which he said that errors in diagnosis were of very frequent occurrence, especially in the earlier period of the disease, and also when it was complicated with pneumonia. A careful physical exploration and the use of the hypodermic syringe, however, would enable the physician to appreciate the real nature of the case. As to the matter of treatment, no medicinal agent would have any effect is producing absorption; but symptomatic and palliative remedies were of service, and it was important that the patient should be

placed in the best hygienic surroundings possible. As regards surgical interference, the more promptly this was made, in general, the better would be the results obtained: provided it was not during the first few days of the attack. As a rule, he had found it better to wait until a week or ten days had passed; so as to allow the acute febrile symptoms to subside, and give the patient a chance to rally. After this judicious delay, aspiration might be tried first; the hypodermic needle having been previously inserted at the point where the aspiration was to be made, in order to be sure of the presence of pus in this situation. Anæsthetics were not required for this operation.

If, after aspiration, the pus was found to be laudable and inodorous, and if it did not accumulate again very rapidly, aspiration might be repeated; but, as a rule, more radical measures were called for. Incision should not be long delayed, because the disease was characterized by fibrinous deposits, as well as purulent effusion, and the fibrine was liable to become decomposed and cause sepsis. The incision should be from an inch to an inch-and-a-half in length, and followed by the insertion of a drainage-tube; after which the cavity should be washed out with antiseptic fluid, and an antiseptic dressing applied. He had found local anæsthesia by cocaine to be all that was required for this operation.

Of thirteen cases in which he had performed it, three had proved fatal, one of the children dying from exhaustion, one from gastro-intestinal catarrh, and one from erysipelas. All but two (2) of the remainder had made perfect recoveries, and the average duration of the trouble was seven weeks. He had used injections of bichloride solution (1 to 5,000) in all his cases, and for the final injection, a solution of half this strength (1 to 10,000). He described the essentials of a good drainage-tube, and said that he was in the habit of employing the plan proposed by Baxton for preventing the tube from slipping into the cavity. The retraction of the chest remaining on the affected side, he had found it could be readily overcome by suitable gymnastics and exercise in the open air.

DR. ROBERT ABBE read a paper entitled

GENERAL CONSIDERATION OF THE SURGICAL TREATMENT OF EMPYEMA.

In the treatment of empyema, he said, it was necessary to abandon all idea of securing absorption, and the first thought should be, how to rid the patient's chest of the accumulated pus most promptly. Aspiration might be repeated a number of times, and in a certain number of simple cases, it was competent to secure recovery. As a rule, it was of more service in children than in adults. It was somewhat repugnant to the surgical mind, however, to leave even a small amount of pus in such a place as the pleural cavity, and if the trouble continued for any length of time after aspiration, complete evacuation should be practised. By far the best results had thus far been obtained with free incision, followed by drainage; and experience showed that the eighth or seventh intercostal space was, as a rule, the best position for the incision. Two large drainage-tubes, of the thickness of the little finger, were usually advisable.

In performing this operation, he used a spray of carbolized solution, of three per cent. strength, produced by means of a simple hand-bulb, and as soon as the flow ceased on inspiration, he dressed the wound with sublimate gauze and iodoform. What we wanted, first and last, said Dr. Abbe, was a thorough outlet, and the purity of the wound was the other important factor. In the great majority of cases, he thought, there was no need of injecting the cavity. When there was a hectic condition, however, antiseptic injections, followed by hot water ones, should be employed; and bichloride solution (1 to 8,000), or a weak iodine solution, might be used for the purpose. Two serious results had been observed from injections; namely, toxic symptoms from the agents employed, and sudden death, due probably to either thrombosis or reflexes from the pleura.

The presence of the drainage-tube occasionally caused denudation of the periosteum of a rib, which had been erroneously designated as necrosis. When this occurred, it was necessary to perform resection, but he considered it unjustifiable to resort to this procedure at first. As regards anæsthetics, a few whiffs of chloroform would answer perfectly well for children, but in adults, local anæsthesia, with cocaine, was preferable. A four per cent. solution should be injected into the tissues, and the incision not made until about fifteen minutes afterward, when the anæsthetic effect had reached its maximum intensity. When there was decomposing fibrin, resection of a piece of rib was sometimes necessary, in order to secure free irrigation, and occasionally, in cases where a suppurating cavity remained after empyema, Estlander's operation of resecting several ribs proved very satisfactory. Dr. Abbe also alluded to "through-drainage" and Hewitt's method of "perflation," the latter of which, he thought, could never supplant free drainage.

DR. THOMAS H. BURCHARD said that he had operated in eleven cases of empyema, all of which were of chronic character. The shortest duration up to the time of incision was two months, and the longest thirteen months, the average time being six or eight months. The youngest patient was three years of age. In all the cases the operation was identical, and all were cases which had previously been aspirated, either by himself or some other physician. He made a free incision from one-and-one-half to two-and-one-half inches in length, along the eighth rib. The amount of purulent fluid evacuated varied greatly. In one boy of seventeen, whose case was one of the most chronic met with, there were only seven ounces, while the largest quantity evacuated was twelve quarts. This was taken from the left chest of a young man of twenty-eight, in whose case one-and-one-half pints had been removed three days previously by aspiration. In this instance, two drainage-tubes six inches in length were employed, and notwithstanding the fact that they were secured with plaster to the chest-walls, they slipped into the cavity during the night. He was not permitted to go on with the case, and it was not until a year afterward that they were removed by resection of the ribs, the operation being performed by the late Dr. James L. Little.

As to the results of his cases, he had followed up seven of them for, at least, one year. Three entirely recovered. Two developed phthisis and died, and a third, a year-and-a-half after the operation, now had phthisis. One died of dysentery of tubercular origin, fourteen months after the operation. In two cases he had observed in children, one of which was among his own cases, and the other of which he had seen in consultation with Dr. J. Lewis Smith, hæmorrhage suffi-

cient to cause death had resulted from the operation; and it seemed to him that this accident was analogous in character to that which sometimes happened in the case of old men, where too sudden and complete evacuation of the bladder was made, resulting in capillary extravasation. In these cases, no artery was cut, and no hæmorrhage occurred from the wound, and he thought the matter was one worthy of serious consideration, especially as he had been able to find no reference to such an occurrence in medical literature. As to the time of performing the operation, he thought it should be done early. If delayed too long, the patient would be liable to die, either of phthisis or tuberculous disease of the bowels.

DR. H. N. HEINEMAN said that empyema in children and empyema in adults were two entirely different affections, and in the former, when it was on the left side, it was very apt to be complicated with pericarditis. Having referred to the differences in the physical signs in the two classes of cases, he said that in children, especially on account of the gurgling met with, the affection was liable to be mistaken for phthisis. The use of the hypodermic needle was always desirable for diagnosis. As regards treatment, the indications had been very well stated by the previous speakers. If, after aspiration, the pus remained sweet, he thought it well to resort to this procedure a second time, after which incision should be practised. In the last ten years, he had made use of only one form of incision, and that was the one known as "thorough-drainage." This had been well described by Chassaignac as long ago as 1857, and he wondered that it had not received more attention than it had, since it was, as a rule, followed by the most satisfactory results.

DR. E. G. JANEWAY, having stated that in his own practice, if one aspiration failed to produce relief, he resorted, with very few exceptions, to immediate incision, spoke of some comparatively rare conditions which had not been alluded to in the discussion. The first of these was empyema as an accompaniment of pyæmia, which was usually due to a gangrenous focus. Again, there were extreme cases in which there were double empyema and purulent endocarditis, where the result was rapidly fatal. There were other cases in which although the fluid was septic, we were debarred from operating, and one of this kind he related. The patient suffered from pneumonia consolidation, pyopneumo-thorax, and sepsis, and the fluid in the chest was very foul. Yet at the highest possible point at which an incision would have been practicable only blood could be drawn with the hypodermic syringe. It was therefore necessary to leave the case to the efforts of nature, and strange to say, the patient had made a complete and perfect recovery. In making an incision it was sometimes necessary to choose a different site from the axillary space, and in such cases we should select the spot where we could get pus. He thought it was a good rule always to insert a hypodermic needle at the point where the incision was to be made immediately before operating.

DR. ALFRED L. LOOMIS said that he had been accustomed to regard the pleurisies of children as very different from those of adults. This, acute suppurative pleurisy was very common in children; and, indeed, whenever he found that a child's chest filled rapidly, he felt pretty confident that empyema was present. The treatment which he adopted in such cases was such as had been described here to-night, and he had found it very satisfactory. But acute suppurative pleurisy in adults was a very different matter. It was a dangerous affection, and often rapidly fatal. He had come to regard it as infectious, and it was usually associated with some acute pneumonia in the other lung. We had, therefore, to contend with an acute disease which could not be shortened by removing the products of inflammation. After the acute stage had passed, however, he believed that incision did good, and was called for. In his opinion, these cases were fibrinous pleurisies at the beginning, and after this condition had continued for about twenty-four hours the chest rapidly filled with pus. Chronic empyema was not a simple pleurisy. We had not merely the pleural cavity to deal with, but a constitutional condition, and it was necessary to seek for the cause of the pus. It was not enough to operate; but, in addition, the physician was called upon to sustain the patient's vital powers in every possible way.

DR. J. WEST ROOSEVELT took exception to the use of the carbolic spray, as advocated by Dr. Abbe, since it was confessedly inefficient in destroying germs; and he also thought that antiseptic injections were entirely useless, on the ground that no solution that could be employed could have any possible effect on the walls of the pleural cavity on account of the thick covering of fibrinous exudations with which they were coated. As to the proposed method of "perflation," he said that if a good way of producing perforation of the lung were devised, he thought this procedure was the one to be adopted.

DR. CAILLE objected to the use of carbolic acid in children on account of the danger of producing toxic constitutional effects.

DR. JOSEPH E. WINTERS said that he had careful records of ninety cases of pleurisy in children, and in only four of these was there empyema. In the latter this condition already existed when the patients first came under observation, and of the remaining eighty-six cases, not a single one terminated in purulent effusion. It was also a fact that not one of these cases had now been lost sight of. Owing to the results thus met with in his experience, he was not able to subscribe to the statements made here to-night in regard to the frequency of purulent effusion in children. In the simple pleurisies commonly met with, he had often seen the temperature go up to 103 and 104; but under the employment of rest, hot applications, and sedatives, the cases almost all terminated in resolution in the course of a week or so. In no instance under his care had empyema resulted. Two cases were operated on on account of the mechanical pressure produced by the large effusion present, and while they both proved fatal, at the autopsy no pus was found in either case.

He had never seen a case of empyema in a child in which there was not an abundance of serum, and he therefore considered that the fluid in such cases was capable of absorption. Hence the condition was very different from that existing in empyema in adults, and he should not deem it necessary to resort to surgical procedures except to relieve the effects of mechanical pressure upon the viscera. Children with empyema invariably lay upon the affected side, and, therefore, in order to facilitate absorption, he encouraged the patient to sit up in bed as much as possible. Dr. Winters decidedly objected to the use of the hypodermic syringe or the aspirator until some such pro-

cedure was absolutely necessary, as he believed that the entrance of the needle into the pleural cavity directly tended to convert simple pleurisy into empyema; and Dr. Francis Delafield, he said, had expressed the same opinion to him. The termination into empyema was, as he had mentioned, naturally very rare in children, but when it did occur, and operative interference was called for, he was emphatically in favor of free incision in preference to aspiration.

DR. HEINEMAN related a case in which there was symptoms of collapse due to hæmorrhage, produced, no doubt, in the same way as in the cases described by Dr. Burchard, in which the child's life was apparently saved by the injection of a certain amount of fluid, which was allowed to remain in the cavity.

The President, DR. A. JACOBI, stated that he had frequently observed severe coughing to be set up by the removal of the fluid from the pleural cavity, and that this could only be arrested by partially filling the cavity again by injection. This seemed to him to be due to the irritation caused by the sudden filling up of the bloodvessels in consequence of the bronchial dilatation resulting from the evacuation.

DR. ABBE said that in his opinion the phenomena sometimes noted after the withdrawal of the fluid were of reflex origin; and he mentioned a case in which there resulted aphonia, disorders of vision, and reflex hemiplegic manifestations.

DR. JACOBI thought the symptoms might possibly be explained by sudden hyperæmia of the larynx, with accompanying anæmia of the brain.

SIXTH GERMAN CONGRESS FOR INTERNAL MEDICINE.[1]

THE sixth congress for Internal Medicine, met in Wiesbaden during the Easter vacation under the Presidency of Professor Leyden of the University of Berlin. The meeting was well attended and full of interest. The therapy of Phthisis Pulmonalis was probably as much discussed as any subject. Fresh air was recommended above every thing else, and a much more favorable view taken of the curability of the disease. One reader said that more than half of the cases not far advanced would submit to cure. Prof. Nothnagel, of Vienna, read on the localization of brain diseases. Prof. Adamkiowicz, of Cracow, read favoring the use of catephoresis in neuralgia. Prof. Mering, of Strassburg, reported some experiments on a dog which promise to throw some light on the dark subject of diabetes.

PROF. HAGENBACH, of Basel, read on

THE PATHOLOGY AND THERAPY OF PERTUSSIS.

He found our knowledge of whooping-cough to be defective and contradictory. For himself he had come to the conclusion that it was a true infectious disease, yet the question always presented itself, Is it a general infection or only a local one; Is the situation of the infectious body to be sought in the nose, larynx or the bronchial tubes? On account of this uncertainty, up to the present time there is no firm basis of therapy. He gave these statistics: according to Uffelmann, 240,000 children yearly contract the disease in Germany. In Basel from 1812 to 1872, whooping-cough was next to typhus and diphtheria in its demands for sacrifices. Out of one thousand deaths in Basel, twelve were caused by whooping-cough. In England, twenty-two, in London alone, thirty-six. The mortality statistics bring into prominent view the fact the younger the child the greater the danger from whooping-cough. The complications also, especially those of the lungs, occur much oftener in the tender years. He considers it an infectious disease, which occurs epidemically, is endemic in large cities, and the infectious material is communicable. The circumstance that having had the disease once, guards against future contraction, speaks for a general infection. The localization of the poison to certain parts of the respiratory mucous membrane, and the usual absence of fever speaks for the local infection.

Rossbach, Rehn, Meyer-Hüni and Von Herff have published the most important results of late. From the most recent of these it appears that the laryngeal catarrh cannot be credited with the important rôle it has thus far held. According to Von Herff and Meyer-Hüni, the spasmodic attack originates from a deep point on the posterior laryngeal wall. Rossbach also considers the catarrh of the bronchiæ as important; at the same time he believes in a reflex neurosis, in which the cough centre is irritated by a specific virus. Others, for instance Baginski, considers it to be more of an infectious catarrh. The nasal theory has found many followers of late. Sommerbrodt, following Hack who first introduced the treatment, has cauterized the corpus spongiosum nasi of children suffering from whooping-cough. Micheal, of Hamburg considers it a reflex neurosis, and treats it locally. We have always believed the fungus will be found in the sputum. The different organisms found so far, have led to no conclusion. Efforts to communicate to rabbits have not been followed by success.

Does the sputum in general contain the fungus? We know the susceptibility to the poison is a general one. It is found in the first year of life, though rarely in the first months; children are most exposed until the tenth year. From this time on, the per cent. of the cases is less and less. The disease is contagious in the first and second stages, generally, so long as mucus is produced and the child coughs. The latter statement is probably too comprehensive, as some children cough long in consequence of complications, the disease having entirely discontinued. The contagium appears able to live outside the human body but a short time. Carrying by means of other persons, does not often happen, while this is well known to frequently occur in scarlet fever. The children are isolated only so far as to keep them from healthy children.

Prophylaxis is not practised as it should be. The kindergartens are to be watched with the greatest care; they form the nests for the plague, more so than public schools, because less under control. Schools should be closed and thorough disinfection practised. The author considered the ordinary plan of a change of air bad practice, while it may be good for the child in question, it has the tendency to spread the disease.

Treatment includes the recommendation of a large number of remedies and plans, which places us on the same ground where we were twenty years ago.

Our treatment, therefore, can only be one ofempiricisms.

So great is the number of means of cure, that it

[1] Specially reported for the Journal.

makes the therapeutist skeptical from the start. The general hygienic treatment is of importance, and above all, is to be urged the plentiful supply of good air. One must take into consideration the climatic and meteorological relations. Especially should this be done in the care of young children. As to the question whether the room should be damp or dry, the author decided in favor of dampness. He thought the good results obtained from hanging cloths wet in carbolic acid about the room, are probably due to the dampened atmosphere.

Among remedies, the narcotics and anæsthetics formerly played a prominent part, and still continue so to do. Indeed, no remedy of this group remains unemployed. It is remarkable, in this day, how little we hear of opium and its derivations, though they are used often enough. Henoch recommends morphia, especially for relieving the urgent symptoms. The author was favorable to this medicine, which shortened the troublesome nights and weakened the attacks, and rendered them less frequent. In France, the medicine recommended by Trousseau, belladonna, is used most frequently. The bromides are given internally, and for inhalation. The author used bromide of potassium in connection with chloral. Gerhardt advised a four per cent. solution of bromide of potassium, with chloral, for inhalation. Lorens and Heubner had good results in shortening the attacks by the use of chloral, in doses of seven-and-a-half to fifteen grains. The latter used it in the evening as an injection. Next to opium, the author had obtained the most benefit from the chloral, with bromide of potassium. Cocaine has been recommended for two years past, especially by Prior. The reporter had found no particular result from painting the parts with a five per cent. solution of cocaine. Ether applied along the course of the vagus by means of the atomizer is recommended, and also nitrate of amyl. Recently, the antiseptic remedies are highly spoken of. Preparations of quinia act against the general infection. Give sulphate of quinia or tannate of quinine. He considers quinine a good medicine, which lightens the attacks and shortens the disease. The tannate of quinine made by Zimmer is much used in Basel. It must, however, often give place to other remedies. In Heubner's critical work, quinia is made secondary to belladonna. Carbolic acid is often used by means of cloths dampened in it, and hung in the room. Also, acid benzoate of soda has its followers. Sonneburg, of Worms, has recently published his success with antipyrine, in which he used it in seventy cases, in doses of four-and-one-half to fifteen grammes. Calomel internally, and gray ointment externally, are highly praised. Letzerich first practised local applications, and in many cases had success with insufflation of quinia. No attacks occurred for a long time after the insufflation; perhaps the quiet came from reaction after the severe irritation of the sensitive-nerve filaments from the insufflation. Painting with solution of quinine is also advised. Hopes are cherished from resorcin in two per cent. solution; still more from salicylate of soda. Heubner has found favorable action from inhalation of salicylin. Of the astringent remedies, Meyer praises nitrate of silver and alum as anti-catarrhal remedies. Michael, of Hamburg, insufflates resin of benzoin with surprising success. In France, boric acid, mixed with roasted coffee, is insufflated.

For a further solution of unanswered questions, we must look to bacteriology and laryngoscopy to obtain a firm basis of treatment.

DR. MICHAEL, of Hamburg, in the discussion which followed, strongly recommended the insufflation of disinfectants in the nose. He had thus treated successfully seventy-five cases out of one hundred. The treatment had proven most beneficial in those cases which had already passed the six weeks, or were just in the beginning. In those patients where every action of the inhalation remained absent in the first few days, he was obliged to resort to other remedies.

PROFESSOR HEUBNER, of Leipsic, believed that all those remedies enumerated in his critical work had little favorable effect on the disease. There was, in his opinion, no single rule, as the severity of the attacks, as well as the duration of whooping-cough, depended on individual surroundings. We must consider the number of the attacks. By this and the duration of the disease, we can know whether we have done good or not.

DR. PRIOR, of Bonn, called attention to the fact that the inspiratory stenotic bruit can be entirely absent in pertussis. There is at present an epidemic in Bonn, where this is absent in the majority of the cases. It is, therefore, not always proper to consider this as a characteristic and diagnostic symptom.

DR. SCHLIEF, of Baden Baden, treated his own child in the pneumatic cabinet. After thirteen sittings, the attacks disappeared. The disease, however, returned in fourteen days, and a few more sittings were necessary to complete the cure. He thought from fifteen to twenty sittings necessary, and considered the action mechanical in that it chemically changed the hyperæmia of the mucous membrane, in consequence of the increased inhalation of oxygen. He had also used inhalations of a four per cent. solution of sulphur.

DR. SONNEBERG, of Worms, referred to his report in the *Deutsche Med. Wochenschrift*, where he used antipyrine with success.

DR. COHEN, of Hanover, called attention to the good effects attained by the inhalation of bromide of potassium and the use of musk.

Recent Literature.

Transactions of the Association of American Physicians. First Session. Washington, D. C., June 17 and 18, 1886.

The first volume of the proceedings of this new Society has made its appearance in the form of a handsome volume of some two hundred and fifty pages. It contains the list of officers and members, the minutes of the first meeting, and the constitution and by-laws of the Association. There are, moreover, nineteen papers on various subjects of general medicine, to the whole of which a copious index is appended. Altogether, the book and the work which it represents are most creditable to the Association, which may now be said to be fairly launched on what promises to be a most successful career.

— The *Lancet* computes that between five and six hundred individuals were treated for various causalties during the procession in London on Jubilee day.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 7, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE FOURTH.

THE glorious fourth of July has passed, and those of us who survive unharmed have reason to be thankful that an opportunity is left us, after the smoke of the celebration has passed away, to count the cost of the exploded gunpowder and moralize over the wounded patriots. Utter recklessness in the use of explosives is not confined to the twenty-four hours that constitute the fourth, but is continued for a space of about three days. During that time it is positively certain beforehand that accidents from fire-arms will be numerous; that a certain number of hands will be disabled; that certain eyes will be destroyed and that a certain number of deaths will follow, if not immediately, yet more or less directly from the accidents during the subsequent weeks. Each fourth of July adds to the number of cripples and dependent persons whose lives are blasted, who are transformed from active producers to mutilated dependents. The character of the injuries has perhaps changed somewhat of late years; the cracker of a few years ago has been supplanted in some measure by the cannon cracker which makes a louder report and explodes with greater violence. The number of casualties due to this giant cracker has been particularly noticeable the present year. It is capable of doing great injury if held in the hand during explosion. The frequency of these injuries is shown by the fact that two men, each one over thirty, lay side by side in the accident room of the Boston City Hospital at one o'clock on the morning of the fourth, each with his right hand destroyed so far as future usefulness is concerned, because he had seen fit to show his patriotism by exploding cannon crackers at midnight and had been foolish enough to allow one to explode while he held it in his hand.

Revolvers and pistols, as a means of celebration have become frightfully common. They are originally produced at low cost, and the boy who cannot obtain a new one can hardly fail to find one discarded by his elders. The pistols are usually claimed to be loaded without balls, but at the close range at which accidents occur, the pasteboard wad penetrates the skin. It may lodge in the flexor tendon of the index finger or penetrate the eyelid and the sclerotic, and destroy the eye. The wounds of the hand made by such wads have of late years been so frequently followed by tetanus as to make them the dread of hospital surgeons. But the use of ball cartridges is not very infrequent, and those who use them exhibit extreme carelessness. It is by no means rare to meet persons injured during the July period of lawlessness by balls which have come from some unknown source.

A procession of those who have been injured by explosives during the gunpowder carnival of the present week in Boston alone, would be a most impressive sight. No immediate deaths occurred so far as is known, this year, but exactly twenty-seven individuals have applied for surgical aid on account of injuries at the Boston City Hospital, and nine beds are at the moment of publication occupied by the victims of casualties. The number treated at the Massachusetts General Hospital is certainly not inferior. Were such a number injured during the same short time, from any cause, at any other season it would be considered something frightful, and public sentiment would demand the instant suppression of the cause. But the half has not yet been told in speaking only of accidents directly from gunpowder. Nor does Boston present an exceptional record.

The disastrous effects of the prevalent methods of celebrating our national *fête* day are unfortunately not confined to the active participants in the demonstration. If a man takes fire into his bosom and his clothes are burned, that result, however lamentable, is not without a certain justice. But we wish to utter a word of protest in behalf of the rights of those who try their best to keep out of the hurly-burly — the non-combatants, so to speak. And our protest is not only for those, numerous as they are, who must annually be shot, singed and mutilated, at the hands of the heedless and irresponsible noise-maker — those we might say who are butchered to make an American holiday, but for the great number of the sick and the feeble whose beds of pain are made racks of torture by the din of horns, powder, nitre, and we believe this year, thanks to the enterprising manufacturer, dynamite. For a week before the day arrives the sporadic and premonitory blasts of the raucous horn are heard. But the distress culminates with the night of the third of July and continues well toward the morning of the fifth. For we have to celebrate not the day of Independence itself but two nights as well.

True that some of the nervously organized are able to hie them away betimes to some quiet spot whereunto the sound of the fire-cracker cometh not. But there still remain through all our cities and towns a great army of sick persons and young children whose welfare is seriously compromised by the noise evolved by the healthy and thoughtless majority. How seriously compromised, can best be judged by the physi-

cians who go their rounds on the fourth and fifth of July to see the tired features to which sleep, however zealously wooed with hypnotic aids, has too long been a stranger. Yearly our police authorities are besieged by anxious requests from apprehensive relatives and from physicians, to abate from some special neighborhood the noise of the Fourth — its preludes and its postludes. But the reply is: not men enough to supply the necessary patrol.

The remedy,— well, that is not so easy to find. So long as every schoolboy can trace his warrant for racketing back to one of the very signers of the Declaration of Independence, we cannot, perhaps, expect much consideration for the welfare of those so unfortunate as to have their season of illness in the early days of July. But both sense and sensibility might combine to restrict the pandemoniac features of the occasion, at most to the one "day we celebrate."

FIRST ANNUAL MEETING OF THE NATIONAL ORTHOPEDIC ASSOCIATION.

THE formation of a National Orthopedic Association is of somewhat more than passing interest. In the last thirty years, this branch of surgery has been developed with a great deal of energy in this country, notably in New York. Any one familiar with the details of the subject and the practice in this department, will have noticed the many improvements in methods which have been introduced into the specialty, so that a relatively new and original school has been formed in America in orthopedic surgery well worthy of the attention of the medical world.

By proficients, it is claimed that all that has been done with us in helping to advance gynæcology to a front rank among the different departments of surgery, is fully matched in the surgery of joints and deformities. The improvements in orthopedic surgery are, however, not as generally known in the profession, for the reason that the glamor (if we may be allowed to use the word in reference to what, to the uninitiated, seems the "infandum" in medicine) which appears to attract a number of general practitioners who interest themselves in gynæcology is not found in a branch where success is won only after thorough and painstaking endeavor carried through a number of years. As few surgeons have worked in orthopedic surgery, few are aware of its successes. It is the object of the new Association to increase the general interest in the department by papers and reports, as well as to gain advantage from each other in the way of stimulus and mutual instruction from personal contact which such associations always give. At the first meeting, papers of a general interest were read by Drs. Morton, Packard and A. S. Roberts, of Philadelphia; Drs. Judson, Gibney, H. L. Taylor, L. H. Sayre, Ketch, Stillman, of New York; Dr. Hodgen, of St. Louis; and Dr. Bradford, of Boston. Dr. Schaffer was elected President of the Association for the ensuing year. We can most heartily wish the new Association success.

MEDICAL NOTES.

— The medical officer in charge of the Marine Hospital Service at Key West reports 51 cases of yellow fever, and 20 deaths, up to June 30th.

— Death occurred recently at University College Hospital from chloroform. The patient was suffering from pleuritic effusion on the left side. A puncture was made, but the fluid did not flow freely, and it was necessary to repeat it. The patient was nervous, and asked for chloroform. The patient died before anæsthesia was complete.

— The *Medical Record* says that a suit was recently brought against the New York Hospital by a patient who had been operated upon for cystitis by cystotomy. The damages claimed were $30,000, on account of impotence from injury of both ejaculatory ducts and wound of rectum. The left lateral incision was made. The plaintiff claimed that, in consequence of the injury, all his semen escaped into the bladder. It was shown by the testimony of Dr. W. T. Bull, the operator, and Drs. George C. Shrady and L. B. Bangs, that such an injury was impossible under the circumstances, and a verdict for the hospital was rendered accordingly.

— In the concluding portion of a continued article on "Fever," published in the *Medical Chronicle*, James Niven, M.B., alludes to the diagnostic interest of the special odors attendant upon some of the infectious diseases. The odor of small-pox, he says, occurs only in the worst cases, and is probably due to a ptomaine generated in the process of necrosis. He then speaks of a peculiar, sweet, almost aromatic odor of the breath that he has noticed in scarlet-fever patients, most marked in the early stages of the disease. A case is mentioned in which a nurse to whom he had pointed out the odor diagnosticated scarlet fever by means of it, in a patient at the height of an attack of small-pox, a whole day before any other scarlatinal symptoms were recognized. Somewhat similar odors are noticed in typhoid fever and measles, but the author says that they can readily be distinguished.

— Mr. Stephen Paget (*British Medical Journal*, March 19, 1887) has, with great diligence, collected no less than 101 cases of parotitis consequent upon injury or disease of the abdomen or pelvis. Of this number, 10 were due to injury or disease of the urinary tract; 18 were due to injury or disease of the alimentary canal; and 23 were due to injury or disease of the abdominal, the peritoneal, or the pelvic cellular tissue. The remaining 50 were due to injury or disease, or temporary derangement of the generative organs. Under the latter term are included slight blows on the testis, the introduction of a pessary, menstruation, and pregnancy. This form of parotitis appears to be non-pyæmic, to have no definite incubation stage, and to end very often in suppuration. Mr. Paget considers that the sequence of disease is due to influences acting through the nervous system.

— We learn from the *Sanitary Engineer* that the

Court of Appeals of New York has lately rendered an important decision in reference to the powers of a town in the matter of the disposal of its sewage. The city of Rochester discharged its sewage into an open drain, which it had constructed across lands situated within the adjoining town of Brighton, and in such wise as to create a nuisance. The town Board of Health thereupon issued an order prohibiting this use of the open drain, but having no power to go within the limits of the city of Rochester, and abate the nuisance by preventing the discharge of the sewage, it brought suit in court against the city for an injunction restraining the discharge of the sewage into the open drain without its own limits, and within the boundaries of the adjoining town of Brighton. The court granted the injunction, and upon ultimate appeal to the Court of Appeals, the action of the court below has been sustained.

— At a recent meeting of the Académie de Médicine, according to the *British Medical Journal*, M. Cornil read a work of MM. Chantemesse and Vidal, upon "River-water and Typhoid Fever in Paris." In this work, the authors prove by statistics the connection between the appearance of typhoid fever, and of the distribution, in Paris, of river instead of spring-water. Pettenkofer's theory of ground-water, together with the discovery of the typhoid bacillus, have led the authors to conclude that, by the diminution in the bulk of water, the pathogenic organisms are concentrated, and, consequently, their dangerous properties acquire greater virulence. Boiling renders the cultivations of these bacilli sterile. M. Léon Colin remarked that the relation existing between the renewed outbreak of typhoid fever in the barracks and the use of river-water had been clearly proved by recent epidemics. River-water is now forbidden for drinking purposes in the barracks. M. Ranse was of opinion than when the administration was obliged to distribute Seine water instead of spring-water, the Paris population should be duly apprised of the fact, in order that proper precautions may be taken.

BOSTON.

— An "agent" is carrying about in this city for the purpose of entrapping the unwary, a hand lens of "400 diameters," whereby he displays the animalcules in "a drop of Cochituate water, that has stood a few days," said animalcules appearing about the size of angle worms. As the lens is of about twenty diameters it is needless to say that the stale "Cochituate water" which he carries for ready demonstration in his pocket is merely a culture medium for pretty gross organic decomposition. The fellow is foolish enough to have visited some physicians, but his victims are likely to be chiefly among the laity.

NEW YORK.

— Dr. Miguel Munez Rossie, one of the leading physicians of Havana, died on the 29th of June, on the steamship *City of Washington*, which had just arrived from Cuba. He had for some time been in bad health.

— At the request of Mayor Hewitt the State Board of Charities is at present engaged in making an investigation into the condition of affairs at the City Lunatic Asylum on Ward's Island, where, it will be remembered, a coroner's jury recently rendered a verdict that the death of one of the inmates was due in great part to injuries received at the hands of two of the attendants. From the testimony that has already been given there can be no question that the institution is overcrowded and that the attendants are insufficient in number, and in certain instances, at least, incompetent; but how far the Commissioners of Charities and Correction and the medical authorities of the hospital are responsible for these evils, it may be somewhat difficult to decide, as the amount of money appropriated for its maintenance is determined entirely by the Board of Estimate and Apportionment.

Miscellany.

A CASE OF TETANUS CURED BY HYPODERMIC INJECTIONS OF COCAINE.

Dr. M. Lopez reports the following case in *El Genio Medico Quirurgico* for February 7, 1887: M. G., fifty, laborer, after working in the wet and cold, complained of rheumatic pains of back and limbs. Three days later, he had marked opisthotonus and painful cramps, and all the symptoms of idiopathic tetanus. Chloral hydrate and morphine were prescribed. For three days the patient was kept under the influence of these drugs, with the result that the pain was lessened, but the muscular rigidity and cramps increased. He now became unable to swallow, and death seemed imminent. Morphine was injected hypodermically, but was followed by no amelioration of the symptoms. Three syringefuls of the mixed solutions of morphine and cocaine (each five per cent.) were then injected. The effect was immediate. After two hours, he could move the limbs, turn in bed, and open his mouth. On the next day he was going on well; slight trismus and stiffness of the neck remained. On both sides of the neck, and at the angle of the jaw, a fourth-part of the syringeful of the same solution was injected. On the next day, all the symptoms had disappeared. The patient rapidly regained strength, and in a week's time returned to work. — *London Medical Record.*

DETECTION OF MORPHIA-TAKING.

The physician who has been worried and deceived by the lying and cheating of the confirmed morphinomaniac or opium-eater, says the *Medical News*, will be grateful for any help toward the diagnosis of this disease, which does not depend upon the morbid imagination or the torpid conscience of the patient. Dr. Oscar Jennings, of Paris, has earned some of this gratitude by following his previous studies of morphinomania with one on its diagnosis and treatment. He suggests, first, the examination of the urine for morphia or opium-salts. The reagents he uses are (1) the double iodide of mercury and potassium (HgCl 13.546,

KI 49.80, H_2O to a quart). This gives a yellowish-white precipitate with the alkaloids. (2) The iodized iodide of potash (I 10, KI 20, H_2O 500), the precipitate from which, in the presence of morphia-salts, is brown or yellowish. If the quantity be too small to discover by one of these reagents, boil the urine to a third, treat with tartaric acid, then dissolve the tartrate of morphia thus formed with amylic alcohol; decompose the salt with ammonia, and if morphia be present, the solution should show a blue color on adding the perchloride of iron. A slightly less troublesome proceeding will detect meconic acid and prove the taking of opium: evaporate, wash with alcohol and boiling water, neutralize with magnesium carbonate, and treat, after filtration, with solution of iron perchloride. A blood-red color is characteristic of meconic acid.

FAMILY PREDISPOSITION TO FRACTURES.

PROF. N. I. STÜDENSKY, of Kazan, adduces an instance (quoted in the *London Medical Record* from the *Dnevnik Kazanskaho Obshtchestva Vratchei*, Nos. 8 and 9, 1886, p. 72) of family fragility of bones. Unfortunately, the details, which concern only father and seven children, are far from being complete. The number of fractures sustained by the family is upwards of fifteen. Here is the list: (1) Father had four fractures (three of the left upper extremity, and one of the femur) during the first five years of his life, while between fourteen and eighteen "he broke many times his legs and arms," and that "always from most trifling injuries, such as making a slip, etc." (2) Second son, at present aged twenty-seven, had six fractures (five of the left forearm, twice both the ulna and radius being broken, and one of the left humerus) during the first six years of life. "All the fractures took place during some harmless plays — from slipping and falling, or from striking his arm against the table's foot, etc." His general state at this time was "satisfactory," but in adolescence he suffered from "extreme anæmia, while now his state is "very satisfactory." (3) Fourth son, always anæmic and emaciated; at three, had a fracture of the forearm (both of the ulna and radius), "from a slow slip on the ice-ground; at five, a fracture of an antibrachial bone from tumbling down during play; at twenty-two, a fracture of his right clavicle from slipping on an ice-glazed pavement. (4) Fifth son, always anæmic, broke one of his forearms in childhood. (5) Seventh son (weak), at five, fractured a forearm, after a trifling fall, when at play in the room.

SOME RARE FORMS OF URTICARIA: GIANT URTICARIA, INTERNAL URTICARIA.

THE *Edinburgh Medical Journal*, June, 1887, quotes from a paper on the above subject by Rapin, in the *Revue Médicale de la Suisse Romande*, No. 17, 1887. The paper, based on eighteen cases, many of which are original, concludes as follows: "Among the various forms of urticaria, there is one remarkable from the considerable dimensions of its patches. It has received, for that reason, the name of giant urticaria. The eruption in giant urticaria may be limited to one or two patches, affecting, sometimes, certain special localities, as the hands, the forehead, the neck. Itchiness, which is regarded, in general, as inseparable from every urticarial eruption, is sometimes absent. The œdema of neuropathic origin, which constitutes urticaria, scarcely pits, and retains but imperfectly the impression of the finger. The absence of these two characters, itchiness and pitting, the result of pressure, have, therefore, no absolute value in the diagnosis of urticaria. Urticaria of the scalp shows itself under the form of hard nodules, resembling the rheumatic nodosites, with which they may be confounded. The production or non-production of pain on pressure, the longer or shorter duration of the phenomena, permit, in the absence of other signs, the differentiation of these two affections. Urticaria does not occur solely on the integument. It is often internal, and has for its seat the mucous membrane of the digestive canal, in any part from the mouth to the intestine. The proofs of this localization are furnished us by the swelling of the tongue and the pharynx, the seat of pain in the course of the œsophagus and in the stomach, and finally, by the digestive disturbances — eructations, vomiting, diarrhœa. The localization of urticaria in the alimentary canal suffices to explain the anxiety and the dyspnœa. The existence of urticaria of the bronchi does not appear to Rapin to have been proved. Urticaria and migraine seem to be related as to their origin, and to belong to the same diathetic stock." Rapin adds: "The supposition of an urticaria of the bronchi does not appear to me tenable, even from a theoretic point of view. In fixing on the pulmonary mucous membrane, urticaria would expose the patient to the danger of asphyxia; its propagation to the glottis would occasion instant death. In point of fact, the prognosis of internal urticaria is not so grave."

THE CONSULTING-ROOM.

DR. DUBRAY has recently published some instructive and amusing advice to a beginner in the profession (*Conseils à un Débutant*), which are referred to in the *British Medical Journal*. The rules about the door-plate, necessary in the provinces, but not considered correct in Paris, concern French practitioners only. Dr. Dubray distinguishes four kinds of consulting-room: the unpretentious, the surgical, the artistic, and the encyclopædic varieties. They are not peculiar to France. In the unpretentious consulting-room the furniture is plain, the book-cases small, and there are just sufficient tables and chairs to allow the patient to sit down and the medical man to write a prescription. The surgical consulting-room presents instruments and appliances scattered about in an apparently artless manner. "Except in the case of a great and celebrated surgeon of admitted renown, an exhibition of this kind is in bad taste," but the exception itself is, perhaps, barely admissible. Complete abstention from parade of instruments is the best rule. It is not advisable to leave hypodermic syringes about the table, with specula serving as paper-weights. These instruments should not, any more than the herbalist's tape-worms and fœtuses in spirits of wine, be made into advertising agents. Even the gynæcological couch should be kept in a corner, and not placed well in the light, displaying a good supply of steps and elevating mechanisms. Such practices savor too much of the crocodile which hung from the ceiling

of the alchemist's laboratory. The term artistic consulting-room, as used by Dr. Dubray, is not quite so innocent in insignificance as it appears. The objects of art are mostly votive offerings of grateful patients, including not only goblets, clocks, and bronzes, but also photographs, with autographs and expressions of gratitude contributed by patients who are distinguished public characters. Were the writer an Englishman speaking of British practitioners, he would add two other examples of art, one of a highly questionable type, the second unquestionably honorable, ornamental, and legitimate. We refer in the first case to framed and glazed diplomas, honorary certificates of proficiency in anatomy, and similar productions which can hardly be classed amongst either literary or artistic ornaments. The second essentially English type of what may be called personal art includes prize cups and other testimonies of the athletic prowess which distinguished the practitioner in the days of his youth. Dr. Dubray rightly condemns an obtrusive display of patient's presents. In the encyclopædic consulting-room, instead of scientific or artistic neatness, the most admired confusion prevails. The tables are strewn with books, pamphlets, and journals, and sheets of manuscript scattered over the ground testify to the literary activity of the practitioner. Dr. Dubray recommends a happy medium. A few artistic adornments, a small library, but not too many books, and no instruments out of their cases should be the essential features of a consulting-room after the most important matter — the arrangement of the writing-table and the chairs in such a position that the patient can sit comfortably in a good light during the consultation.

REPORTED MORTALITY FOR THE WEEK ENDING JUNE 25, 1887.

Deaths reported 2,274: under five years of age 1136; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 636, consumption 308, lung diseases 131, diarrhœal diseases 380, diphtheria and croup 122, measles 25, typhoid fever 25, scarlet fever 23, malarial fever 16, cerebro-spinal meningitis 12, whooping-cough 15, erysipelas eight, puerperal fever eight. From typhoid fever, Philadelphia 12, New York four, Pittsburgh three, Lowell two, Baltimore, New Orleans, Nashville, and Charleston one each. From scarlet fever New York 12, Philadelphia four, Baltimore three, Boston two, Pittsburgh and Nashville one each. From whooping-cough, Philadelphia five, New York three, Baltimore two, Richmond, Boston, New Orleans, District of Columbia and Nashville one each. From cerebro-spinal meningitis, New York five, Lowell two, Philadelphia, Boston, District of Columbia, Milwaukee and Holyoke, one each. From malarial fever, New York nine, New Orleans three, Baltimore two, Philadelphia and Richmond one each. From puerperal fever, Philadelphia, Pittsburgh and Milwaukee two each, District of Columbia one. From erysipelas, Philadelphia two, New York, New Orleans, District of Columbia, Pittsburgh and Milwaukee one each. From small-pox (New York) two.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,089, for the week ending June 11th, the death-rate was 18.4. Deaths reported 3,340; infants under one year of age 789; acute diseases of the respiratory organs (London,) 259, measles 227, whooping-cough 127, scarlet fever 55, fever 31, diarrhœa 29, diphtheria 17.

The death-rates ranged from 11.3 in Leicester to 29.4 in Birkenhead; Birmingham 16.6; Bradford 17.4; Derby 13.9; Hull 17.8; Leeds 18.9; London 17.5; Manchester 23.9; Newcastle-on-Tyne 26.6; Nottingham 15.1; Sheffield 21.0; Sunderland 19.7.

In Edinburgh 21.0; Glasgow 22.6; Dublin 31.2.

The meteorological record for the week ending June 25, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, June 25, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING JUNE 25, 1887.

GUITERAS, JOHN, passed assistant surgeon. Detailed for temporary duty at Key West, Fla., June 23, 1887.

WASDIN, EUGENE, passed assistant surgeon. Relieved from duty at Marine Hospital, New York, N. Y., ordered to Marine Hospital, Chicago, Ill., June 23, 1887.

NORMAN, SEATON, assistant surgeon. To proceed to Charleston, S. C., for temporary duty, June 23, 1887.

HEATH, F. C., assistant surgeon. Relieved from duty at Chicago, Ill., June 23, 1887.

APPOINTMENTS.

Dr. C. B. Porter has been appointed Professor of Clinical Surgery, and Dr. J. C. Warren Associate Professor of Surgery in Harvard University. Dr. H. L. Burrell has also been appointed Demonstrator of Bandaging and Apparatus, and Dr. G. H. Monks Instructor in Surgical Pathology.

DEATHS.

Died at Belmont, N. H., Charles Warren Hackett, M.D., M.M.S.S., of Maplewood, aged thirty-five.

Died in Middleboro', Mass., June 28, 1887, Ebenezer Wade Drake, M.D., M.M.S.S., aged sixty-nine years.

BOOKS AND PAMPHLETS RECEIVED.

The Fourteenth Annual Report of the Board of Health of the City of New Haven. 1886.

The Uses of Adhesive Plaster in Orthopædic Surgery. By A. B. Judson, M.D. 1887. (Reprint.)

Announcement of the Western Pennsylvania Medical College, Pittsburgh, Pa. Sessions of 1887–8.

Dr. Didama's Introduction to a Discussion on Tubercular Consumption. Syracuse, N. Y. 1886.

Announcement of the Oliver Wendell Holmes Hospital. Hudson, St. Croix County, Wisconsin, 1887.

Transactions of the American Ophthalmological Society. Twenty-Second Annual Meeting. New London, Conn., 1886.

Maternal Impressions. Discussion on Dr. Barker's Essay. By Samuel C. Busey, M.D., Washington, D. C. 1886. (Reprint.)

Woman's Medical College of the New York Infirmary. Nineteenth Annual Catalogue and Announcement. New York, 1887.

University of the City of New York. Medical Department. Forty-seventh Annual Announcement of Lectures and Catalogue. Session 1887–88.

Catalogue of the Albany Medical College, Medical Department of Union University. Fifty-sixth Session, 1886–87, and Announcement for Session, 1887–88.

Abstract from the Transactions of the Medical Society of the State of New York, for the Year 1887. Merritt H. Cash Prize Essay; the Physiological Conditions and Sanitary Requirements of School-Houses and School-Life. By A. N. Bell, A.M., M.D., Brooklyn, N. Y. 1887.

Forty-first Annual Announcement of Starling Medical College, together with Catalogue and Order of College and Hospital Exercises for the Session of 1887–8. Columbus, Ohio.

De la Jugulation de la Fièvre Typhoide au Moyen de la Quinine et des Bains Tiedes. Par Le Docteur G. Pécholier, Professeur Agrégé a la Faculté de Medecine de Montpelier. 1887.

Report of the Board of Censors to the Maine Medical Association at its Thirty-Fifth Annual Meeting held at Portland, June 14, 1887; containing the Committee's Report on the Status of the Registration Act.

The Causes and Prevention of Infantile Diarrhœal Diseases. By F. R. Campbell, A.M., M.D., Lecturer on Hygiene, Niagara University, Sanitary Inspector of the Board of Health, Buffalo, N. Y. Buffalo, 1887. (Reprint.)

Practical Urine Testing: a Guide to Office and Bedside Urine Analysis for Physicians and Students. By Charles Godwin Jennings, M.D., Professor of Chemistry and of Diseases of Children, Detroit College of Medicine, etc. Detroit: D. O. Haynes & Co. 1887.

A Manual of Treatment by Massage and Methodical Muscle Exercise. By Joseph Schreiber, M.D., Member of K. K. Gesellschaft der Aerzte of Vienna, etc. Translated with the Author's Permission by Walter Mendelson, M.D., of New York. Philadelphia: Lea Brothers & Co. 1887.

Treatment of Disease in Children, including the outlines of diagnosis and the chief pathological differences between children and adults, by Angel Money, M.D., M.R.C.P., assistant physician to the hospital for sick children, Great Ormande St., etc. Philadelphia. P. Blakiston Son & Co., 1887.

Statistique des Vaccinations Pratiquées avec la Culture Attenuée Du Microbe de la Fièvre Jaune de Septembre, 1885, à Septembre, 1886. Par le Dr. Domingos Freire, Professeur de Chimie organique et biologique à la Faculté de Médecine de Rio-de-Janeiro, etc. Paris Libraire J. B. Baillière et Fils, 1887.

What to do in Cases of Poisoning. By Wm. Murrell, M.D., F.R.C.P., Lecturer on Pharmacology and Therapeutics in the Westminster Hospital, etc. First American from Fifth English Edition. Edited by Frank Woodbury, M.D. Published by the Medical Register Co. Philadelphia, 1887.

Practical Lessons in Nursing. Outlines for the Management of Diet: or the Regulation of Food to the Requirements of Health and the Treatment of Disease. By Edward Turvis Bruen, Assistant Professor of Physical Diagnosis, University of Pennsylvania, etc. Philadelphia: J. B. Lippincott Co. 1887.

Resident Students of the Charity Hospital of New Orleans, Louisiana. Establishment of a Medical Library, by the Louisiana State Medical Society. By Joseph Jones, M.D., President of the Louisiana State Medical Society, Visiting Physician of the Charity Hospital of New Orleans, etc. 1887. (Reprint.)

Anatomische Untersuchungen am Menschlichen Rectum und Eine Neue Methode der Mastdarminspection von Walter J. Otis, M.D., aus Boston. Erster Theil; die Sacculi des Rectum. Mit einem Holzschnitt im Text und Acht Tafeln. (Aus dem anatomischen Institut der Universität. Leipzig: Veit & Co. 1887.

A New Explanation of the Renal Troubles, Eclampsia, and other Pathological Phenomena of Pregnancy and Labor. By A. F. A. King, M.D., Professor of Obstetrics, etc., in the Medical Department of Columbia University, Washington, D.C., and in the University of Vermont; President of the Washington Obstetrical and Gynecological Society, etc. New York: Wm. Wood & Co. 1887. (Reprint.)

Original Articles.

ALCOHOL AGAIN: A CONSIDERATION OF RECENT MISSTATEMENTS OF ITS PHYSIOLOGICAL ACTION.[1]

BY JOSEPH W. WARREN, M.D.,
Assistant in Physiology in the Medical School of Harvard University.

A substance which is disposed of as completely as is alcohol by the human body, might be expected to exercise some influence on the nutrition. A large number of cases are cited by Anstie (in his "Stimulants and Narcotics") all showing that a human body well supplied with alcohol may get along very well or fairly well without the ordinary quantity of food. The clinical experience with alcohol, under conditions where it could not merely act by aiding the patient to absorb more food, also suggests that it may, at least at times and to some extent, take the place of acknowledged foods. In much of the discussion on this point, it seems but too often overlooked that alcohol, as a non-nitrogenous substance, could not be expected ordinarily to actually take the place of all and every food for a long time. It does not surprise us that men do not get on very well when fed on fat or sugar only, why should we expect them necessarily to thrive on alcohol? It is, however, a matter of common experience that people do thrive and keep perfectly well who use a moderate amount of alcohol in the form of various beverages. Some of these contain other substances of unquestioned nutritive value. The fact must not be overlooked that there are millions of people in this country and millions in Europe who constantly take small quantities of alcohol in some form and who are absolutely in no way the worse for so doing. It will not do to point to the drunkards, whether of the fat and lazy type or not; it will not do to urge that organs degenerate as a result of alcoholic excesses; these things merely have a value in enabling us to draw some line as to what is reasonable and prudent, but they do not demonstrate the injuriousness of the substance properly used. It is easy to find instances where acknowledged foods are abused. All about us are men who undoubtedly eat too much, or do too little, or both. There is good reason to believe that many persons drink too much water, while the abuse of coffee and tea is very frequently observed. It would be easy to multiply the instances where the good things of life, which are also its necessities, are abused, but no one ventures to infer that these things are therefore harmful. The degenerations of phosphorus poisoning are never advanced as an objection to the acid phosphates of Tom, Dick, and Harry, nor as showing the harmfulness of such phosphorus acid as is in accepted and traditional foods.

The experimental determination of the position of alcohol as a food, has hitherto met with great difficulties. Its disappearance suggests that it *may* play a part in the economy of the body in one of several ways. If it be burned up in the body, that is, completely oxidised to carbonic acid and water, as seems highly probable, we should not only have the development of a great amount of force, but we should also expect to find the products of this combustion, and these have not as yet been satisfactorily made out. There are, however, a number of good reasons for this, and it by no means follows that they do not exist.[31]

As there is no nitrogen in alcohol itself, we may not expect any direct effect from the oxidation of this substance on the nitrogenous excretion. Indirectly, the influence might be either to increase or to diminish it. Alcohol might work unfavorably on the metabolism, causing more extensive tissue change and consequently an augmentation of the nitrogen output; or it might for some reason, while increasing the destruction, hinder the outflow, but this view is exceedingly improbable, and has no good foundation. On the other hand, the combustion of the alcohol may take the place of the oxidation of the nitrogenous substances (just as it may be easier at times to burn the wood a household happens to have at hand and spare the supply of coal); this would lead to a diminished excretion of nitrogen. Simple as the problem appears, the solution has not yet been reached. A large number of observers report a distinct diminution of the nitrogen output. Even Dr. Davis admits this, but he interprets it ingeniously as a retardation of "those molecular or atomic changes which constitute nutrition, disintegration and secretion, and on which the phenomena of life depend," and also as a retardation of the "elimination of waste matter." This, in very plain English, is much the same as saying that a family which happens to use a gas stove for a few days, ought to have as full an ash barrel as when using the ordinary range, otherwise they fail to eliminate the waste matter of the coals which they have not as yet burned! Although personally, I am inclined to think that there really is a diminution of the nitrogen outgo, I do not think that the evidence at our disposal fully proves it. None of the older experiments have much value now. We have learned, within a comparatively few years that to understand the nitrogenous metabolism the body experimented upon must be brought into nitrogenous equilibrium before any drug or other influence can be tested. Before studying a drug we must have been able to find all the nitrogen that goes into the body in the urine and in the fæces, otherwise no fair inference can be drawn, because the body may be adding to its own albuminous material. And when we have this equilibrium we must still know not merely the nitrogen of the urine but also that of the fæces. Evidently it is not enough to ensure a regular and measured diet, from which an unvarying import of nitrogen is inferred. All this was unknown to the older experimenters, and very much limits the value of their work, however excellent it was in its own day. It has also often not been duly considered in much work of a more recent date.

It is for these reasons, (and I think they are not finical), that we are not justified in accepting as conclusive, many experiments commonly referred to as showing a reduction of the metabolism with reference to nitrogen, under the influence of alcohol, that is, a saving and storing up of albuminous material. To these belong the elaborate work of Böcker[32] (who

[1] Concluded from page 6.

[31] Thompson (Is Alcohol a Food? Lancet, 1885, I, 743), has suggested an ingenious plan to determine whether alcohol can act as a food. He argues that alcohol ought to appear in the urine more readily when the body is fully supplied with food than when there is a deficiency (as with little food and much exercise), which it may make up. A couple of experiments seem to corroborate this view, but evidently there are too many sources of error in the method there employed.

[32] Böcker: Beitrage zur Heilkunde, 1849, vol. I, 240. It is, of course, easy to sneer, now, at work of this description which in its day and generation was unquestionably on a high level. I have no desire to speak of such investigations otherwise than with respect. What ought to meet with vigorous opposition is the fact that a

seems to demonstrate a great falling off in the elimination of nitrogen, but with absolutely no control over the amount of nitrogen entering the body), that of Duchek, the investigations of Hammond[33] (with an apparent lessening of the nitrogenous excretion in the urine of about thirteen per cent.), those in the first three articles by Parkes noted above, (with practically no change in the urea outflow), and the more recent researches of Riess[34] (a lessening of fifteen to twenty-two per cent.).

In fact, almost the only experiments in which the nitrogenous equilibrium seems to have been carefully established are those of I. Munk[35] on dogs. Some earlier ones made by Fokker, and which appear to have been good (showing a diminution of from six to twenty per cent.) are, unfortunately, not easily accessible to me now. Munk found that moderate doses of alcohol diminished the nitrogen of the urine from six to seven per cent., while larger doses (not lethal, but producing much depression and insensibility) caused an increase in the nitrogenous output of from four to ten per cent. An independent confirmation of these results would be very desirable. It may be that alcohol can protect the consumption of other substances to some extent, but that large amounts either injure living tissues, or cause a destruction of albuminous material not yet worked into the living protoplasmatic network of the body.[36]

The metabolism of the body is not measured by the excretion of nitrogen alone, but also by the amount of carbonic acid sent out. Many writers are disposed, nowadays, to attribute the latter to the oxidation of fat and carbo-hydrates, and to speak of the former as due to the transformation of albuminous substances. Such a view I believe to be exceedingly incomplete and unsatisfactory, but it would lead too far to consider that question now. Whatever the origin of the substances may be, there is no question that their formation goes on in such a way that the carbonic acid may be considered to be, in general, quite independent of the urea.

At the first glance, it would appear to be simple enough to determine this carbonic acid excretion, and to draw inferences from it. Indeed, there are numerous older observations where such a course was pursued. It has turned out, however, to be of prime importance to know the amount of oxygen taken into the body, as well as the amount of carbonic dioxide excreted.[37]

A body like alcohol, burning readily and completely to carbonic acid and water, might be expected to demonstrate its combustion by affecting the CO_2 excretion, and many observers have sought to determine this experimentally. For various reasons, no satisfactory unanimity of results has as yet been attained. The older observations are often inexact in method, although they generally show a diminution in the CO_2 output. To these belong the experiments of Prout,[38] Fyfe,[39] Vierordt,[40] Böcker, Davis, Hammond, and others, in which there was absolutely no determination of the oxygen, and the collection of the carbonic acid was made in such a way, or for such periods, as seem too little exact and sufficient. The ingenious and elaborate researches of Smith[41] also fail to give the information we want concerning the amount of oxygen taken in. For the carbonic acid excretion, it was found that it is increased by spirits of wine and most beverages containing alcohol, but diminished by brandy, gin, and some specimens of whiskey.

Berg,[42] who also found the absolute amount of carbonic acid increased after alcohol, does not appear to have made any determination of the oxygen.

Among the more recent investigators with exacter methods, Boeck and Bauer[43] found that alcohol in small doses diminished the O_2-inflow and the CO_2-excretion (about 20 per cent.) while larger quantities (without narcosis) caused an increase as regards both substances of 12–34 per cent. Only two experiments (dogs) are reported, but the authors say they obtained similar results on other dogs and cats. In some cases there appears to have been distinct intestinal disturbance, and this would probably affect the CO_2 production.[44] In one of the two cases the increase of oxida-

teacher should cite such experimental work of an older date as valuable, and yet draw no distinction between it and that done in recent years with the most carefully elaborated methods, or even neglect to mention the latter altogether.

[33] Hammond: The physiological effects of alcohol and tobacco upon the human system. Reprint from the American Journal of Medical Sciences for 1856, in his Physiological Memoirs, 1863, p. 43. Hammond's urea determinations have not met with universal acceptance. Cf. Speck: Arch. f. exp. Path. u. Pharm., xv, 95.

[34] Riess: Ueber den Einfluss des Alkohols auf den Stoffwechsel des Menschen. Zeitschr. f. klin. Med., 1881, vol. II p. 1. Binz (Vorlesungen p. 361, and again quite recently in the Centralblatt für klin. Med. for May 7, 1887.) seems to consider Riess's results satisfactory. I must observe, however, that the men examined were convalescents (from rheumatism and subacute myelitis), that although they were placed upon a carefully measured diet the nitrogen of this was not determined, and that the men were admittedly not in nitrogenous equilibrium.

[36] The presumption that alcohol lessens the amount of oxidation in the body, in the sense of saving material, not of retaining "effete, waste substances," is strengthened by some interesting observations on the conversion of benzol to phenol and related products in the body. Nencki and Sieber (*a*) had shown that, normally, a pretty constant relation existed between the amount of benzol (C_6H_6) introduced into the body and the phenol (C_6H_5·OH) found in the urine. Then Simanowsky and Schoumoff (*b*) found that alcohol lessened this transformation for rabbits, dogs, and for man.

[37] The relation of these, $\frac{CO_2}{O_2}$, is now commonly called the respiratory quotient; it expresses the amount of oxygen returned as carbonic acid, any deficit being used presumably for other oxidations.

[38] It is an entertaining illustration of the danger that lurks in citations, that Dr. Davis speaks of Prout as overthrowing, "by direct experiment," the theory of Liebig after it was proposed, Prout, as a matter of fact, having made his investigations when Leibig was not yet ten years old. Dr. Davis (in common with many others, for example, Wolters) has been misled by a quotation in the second volume of the London Lancet (1843, p. 17). Prout's articles — "Observations on the Quantity of Carbonic Acid Gas emitted from the Lungs during Respiration, at different Times, and under different Circumstances" — are in Thomson's "Annals of Philosophy," 1813-14, Vol. II, p. 328, and Vol. IV, p. 331. Interesting as his work is, it has, of course, now only historical value. Any deductions which modern writers may wish to make from it must be modified also by Prout's statement (p. 336 of the second article) "that they (the numbers in his paper) do not represent the measures of the quantity of carbonic acid emitted *in* any given time from the lungs, but the measures of the power or capability of the lungs, *at* any given time, to form or throw off carbonic acid. What I mean to say is this: that the *power* or *capability* of the lungs for forming and throwing off carbonic acid is *greater* at noon, etc., and not that a greater quantity of it is *actually thrown off* at that time than at any other. A greater quantity will, indeed, be thrown off, cæteris paribus, on an equal number of similar respirations being made in the same given time; but whether this be really the case or not, I cannot pretend to determine."

[44] Zuntz and v. Mering (Pflüger Archiv, 1883, xxxii, 173) have shown that the work of the digestive act (and apparently any irritation of the tract) causes an increase in the amount of oxygen taken into the body.

tion is not convincing, for a change nearly as great occurs apart from any alcoholic influence.

In 1883 Henrijean published a preliminary communication [45] concerning experiments made on himself in Fredericq's laboratory at Liége, in which he found that the oxygen taken into the body was, on an average 19 per cent. greater in amount after taking alcohol than in hunger, and the increase after taking a moderate breakfast was about 23 per cent. The increase under alcohol seems to continue too long to be due to the action on the intestines; in fact the average for the later determinations (80–180 minutes after taking) is rather higher than for the earlier ones. No determination of the carbonic acid was made.

At about the same time Wolfers [46] published some experiments which he had made under Zuntz's guidance a couple of years before. He used rabbits which were sunk in a bath at a constant temperature. The alcohol was introduced sometimes through a vein, in some experiments directly into the stomach. The doses were large although narcosis does not seem to have been usually produced, nor considerable muscular movement avoided. Wolfers found that the consumption of oxygen increased under alcohol; the output of carbonic acid was also increased, but less extensively; the respiratory quotient was usually lowered. From this the inference is drawn that the alcohol is partly oxidized in the body, but that no lessening of the oxidation processes may be attributed to it. But even if more oxygen be consumed it does not follow that the increased oxidation may not be that of the alcohol, and at the same time include a protection of the tissues.

Against these experiments it has been argued that the animals were rabbits and fastened down in an unfavorable manner. On the other hand Zuntz has urged that perhaps the rabbit from living so largely on carbo-hydrates may be especially adapted to show the influence of alcohol in the respiration.

We have also incidental information in a research by Rumpf,[47] who found that in alcohol narcosis the temperature of guinea pigs is much lowered, and its regulation disturbed, and the oxydation as represented in the oxygen consumption greatly reduced. Obviously the conditions were such as to permit no fair inferences concerning the physiological action of alcohol.

Still more recent are experiments in this direction made by Bodländer, Zuntz (with Berdez), and Geppert.

Bodländer [48] worked with a new apparatus, which has the advantage of leaving the animal perfectly free in a small chamber and undisturbed by any operation for the introduction of breathing tubes and the like. Bodländer found the oxygen consumption reduced for two dogs, 12 per cent. and 19 per cent., the CO_2-excretion 11 per cent. and 19 per cent., the same changes for a rabbit being only 3 per cent. and 8 per cent. respectively. There is, then, a small lessening of the respiratory quotient for the rabbit and no such change for the dogs. But as Zuntz has pointed out, in the article mentioned below, Bodländer's dogs had a very high oxygen consumption in the "normal" experiments which leads to the inference that they were more restless than the experimenter supposed (and any muscular action is a most potent factor in the O_2-consumption) and that the influence of the alcohol was to lessen their activity, and consequently to reduce the respiration. Zuntz also objects to the imperfect ventilation of Bodländer's apparatus, and thinks that the lowering of the temperature of the animals would also tend to lower the oxygen consumption, it having been shown by Pflüger and Velten that a reduction of 1° C. lessens this about 5 per cent.

In Zuntz's experiments with Berdez [49] the latter breathed through a carefully fitted tube with valves, the nose being closed. It was thus possible to ensure perfect muscular quiet and examine the course of the respiratory change for twenty minutes at a time. The outcome of the very few experiments which could be made was that "none of the important factors of the respiratory process was lowered." The oxygen inflow rose about 3.5 per cent., the carbonic acid outflow increasing also about 4.5 per cent. The smallness of these figures as compared with those of Wolters is attributed to the small amount of alcohol which Berdez was able to take without causing muscular unrest.

The latest and in some respects the most interesting experiments are those which Geppert [50] has published, while I was collecting the material for this paper. Geppert has a new and very ingenious apparatus for making respiration experiments on man. This renders it possible to exclude many disturbing factors which are met with in experiments on animals and are there often beyond the control of the experimenter. Excluding all cases where the alcohol caused muscular disturbance or produced sleep (since both conditions have nothing to do with the alcohol effect on respiration for itself) it was found in a number of experiments on four men that "the doses of alcohol employed had no important effect on the oxygen consumption." The carbonic acid excretion was not increased; it was either constant or somewhat lessened. In fact the respiratory quotient appears to me to have been in every case slightly lowered. This may be interpreted to mean that the oxidation of the alcohol has protected some other substance from oxidation and lessened the amount of oxygen which appears in the expired air as CO_2. When carbo-hydrates are consumed the oxygen of the CO_2 sent out is equal to the oxygen taken in for the combustion, its respiratory quotient is said to approach 1.00; the combustion of alcohol on the other hand returns in the form of carbonic acid, but two-thirds of the oxygen taken in, it has a respiratory quotient of 0.66.

It will thus be seen that we are not as yet in a position to make very positive assertions concerning the influence of alcohol on the tissue changes as measured by the respiratory gas exchange or in terms of nitrogen excretion. An ingenious advocate could draw arguments for either side from the experimental evidence at our disposal. But we should be extremely cautious in inferring the physiological influence from those very common results of unwise indulgence in alcoholic beverages, and which are clearly pathological. The imperfect nourishment of many drinkers is explicable by the chronic disturbances of the intestinal

tract with the attendant upsetting of digestion and absorption. This, too, is often enough further complicated by a real insufficiency of food either in quality or quantity. The excessive formation of fat with accompanying degenerations often attributed to alcohol is certainly not always due to its moderate use alone (although even this, in some persons favors obesity); unwelcome or dangerous fatness is often enough met with where there is a complete disuse of alcohol.

Concerning the action of alcohol on the muscles, exceedingly little is really known. Nearly all the experimental researches merely show that quite concentrated solutions of alcohol kill muscular tissue, cause rigidity or hasten it, and precipitate or coagulate the albuminous substances. This is not only what might be expected, but also demonstrates actually nothing concerning the behavior of such quantities as would reasonably and probably reach the muscles. It has, for this purpose, no more value than the platform trick of coagulating egg albumin in a tumbler by spirits of wine, which, I am told, some audiences have found to be very impressive.[51] There is, however, some reason to believe that the use of alcohol (certainly when given in rather large doses to healthy persons) does not enable a man to do more hard work with his muscles, at least, for any length of time.[52] This effect is probably complicated by the influence of alcohol on the nervous system.

One of the most delicate reagents which we have for alcohol, or rather, for alcoholic beverages, is the human central nervous system. As a noted anatomist used to say of the external ear, this can be best studied on one's neighbors. It seems hardly necessary to point out that the effect first manifests itself in the cerebral centres, and that this, for a small amount, is a stimulation.

"It is very difficult to say how far the stimulating action depends on the increased circulation through the nervous centres only, or how much of it may be due to the action of the alcohol on the nervous structures themselves. The symptoms of intoxication must, however, be referred to a paralyzing action of the alcohol on the nerve-centres, for, although as intoxication progresses, a diminution in the activity of the cerebral circulation occurs, and the well-nourished brain becomes anæmic, this alone is insufficient to account for the effects we observe. The first of these are weakening of the mental faculties and of the power of coördination. The higher faculties seem to go first, and a man's judgment becomes impaired, while his memory and imagination are still more lively than usual. Then these faculties diminish, and the emotions become more prominent, so that a man is either ready to swear eternal friendship all round, or becomes as anxious for a fight as an Irishman at Donnybrook; is gay, mirthful, and hilarious, or subdued and lachrymose, melting into a flood of tears without any apparent cause. At the same time, the power of coördination becomes impaired. This is most evident in the tongue and legs, the speech becoming thick and indistinct, so that the pronunciation of the words 'British Constitution' becomes next to an impossibility, and locomotion becomes staggering and uncertain. Although loss of the mental faculties and loss of coördination power generally go hand-in-hand, yet either of them may occur a good while before the other, so that persons who seem stupefied by drink may rise and walk with the utmost readiness, while others, who seem perfectly unaffected while sitting, and can discourse on any subject with freedom, will find great difficulty in steering their way from the table to the door." (Brunton.)

Although the course of the influence is clearly perceptible, such attempts as have been made to define or measure it experimentally have not been remarkably successful. The observations of Exner,[53] Dietl and Von Vintschgau,[54] and Kraepelin,[55] seemed to show that the reaction time (that is, the time required to perceive an appointed signal, and make a simple predetermined signal in reply) may be quickened by alcohol or alcoholic beverages, but that there follows ere long a period of slower replies, and that such a slowing occurs rapidly from a large dose.

Some experiments of my own, which will shortly be published, appear to demonstrate that the influence of alcohol in this respect is even more varied than has been supposed, and that no final conclusions can be drawn at present. I can see no valid reason for supposing that alcohol does not quicken mental activity (where there is any to be quickened). The stimulating influence of small quantities of alcoholic beverages is a matter of too common experience among brain-workers to permit a wholesale denial of it. Obviously, this results from a variety of causes, and is subject to enormous individual variations and limitations, and the bad effect of large quantities is beyond question. It will not do to urge, as is usually done, that mankind was mistaken as to the influence of alcohol on the body-temperature, and so must be about the effect on the brain. A man's knowledge of his temperature is exceedingly limited, quite subjective, affected by many influences, and altogether uncertain; he merely knows that he feels warmed. But if we test the temperature by a thermometer, why may we not judge somewhat of the mental effect by the work which is done under such circumstances? Looked at in this way, there is experience enough to warrant us in saying that very often men really do think better and write better with moderate alcoholic stimulation than without it. It does not in the least follow from this that constant stimulation for such a purpose is good or permissible any more than it does that a man should always run when he can just as well walk, although progression would thus be more rapid for a time.[56]

[51] Engelmann (Ueber die Flimmerbewegung, 1868, p. 58, and in Hermann's Handbuch der Physiologie, I, 402) has shown that small doses of alcohol increase the frequency and energy of ciliary motion, while large doses bring it to a standstill. Dogiel, too, asserts that the force of muscular contraction is similarly affected. His paper (Pflüger's Arch., viii, 606) is, however, but an abstract so brief and aphoristic, that it affords no chance of judging of its true value.

[52] Parkes, in the first paper quoted above, tested the muscular power of his soldier (probably with a dynamometer), and found that no change was produced by alcohol. In one of the later series of experiments, where the soldier labored hard with the spade, he worked (in his opinion) very much less well with brandy than without it, but the quantities which led to this result were considerable. This view is also favored by his paper in the Lancet (1874, ii, 238, 263, "Report on the Issue of a Spirit Ration during the march to Coomassie,") which presents evidence that the use of alcohol does not, on the whole, enable soldiers to endure more fatigue, except when taken *after* the work of the day is done. But even here, the evidence is not altogether convincing to those who are not professional temperance agitators.

[55] Kraepelin. Wundt's Philosophische Studien, 1881-83, I, 573.

[56] As to any special action on nerves and nerve-centres, there may be added the declaration of Dogiel that the irritability of motor and of sensory nerves is, at first, increased and then diminished, and that the reflexes of beheaded frogs are, at first, quickened and then slowed. On the other hand, Meihuizen (Pflüger's Archiv, 1873, vii, 217) found that these reflexes were much slowed at first, and for a considerable period, being followed by a considerable quickening, but he got these results with what must be considered a large dose, and got less constant ones when the quantity of alcohol was only half as great. Kremer's observation (Pflüger's Archiv, 1884, xxxiii., 288) that

But I am wandering too much from my original purpose, yet I trust that the effort not merely to examine some of the older experimental foundations for an opinion about alcohol, but also to inquire what the most recent work has done to strengthen or to weaken them may not be altogether unwelcome to any reader who may chance to have followed me thus far. I hope that I have made it clear that the statements of Prof. N. S. Davis, so far as they have to do with the physiological action of alcohol, are not in accord with the knowledge available when the tract was printed, and are also not supported by the more recent investigations. The points which I should like to insist upon, in recapitulation, are these:

(1) That alcohol enters the animal body readily, and is there very completely disposed of.

(2) That the oxidation of such a substance may fairly be expected to develop force, and that although we cannot as yet say just how this takes place and just what it accomplishes, we have no right to deny that it does occur.

(3) Our knowledge, such as it is, of the influence of alcohol on the muscular and nervous structures of the body, on the function of digestion and absorption, on the heart and circulation, on the heat-production and regulation, on the tissue changes (the metabolism) of the body, and on the psychic functions, does not warrant us in saying that the really moderate use of alcohol is harmful, not to say dangerous, from the point of view of the physiologist.

But we are told, "Wine is a mocker, and whoso is deceived thereby is not wise." Well, there are a good many "mockers" nowadays. Beef tea is one of them. Various artificial foods and similar preparations belong to the same category. It is an exceedingly unfortunate thing, doubtless, to be deceived by these things, but I cannot help feeling that it is a much worse thing to be a deceiver concerning them. I have an impression that the same "wise man" has also urged men "to buy the truth and sell it not." There are times, perhaps, when it is well not to tell the whole truth, but I have yet to learn how the human race can be benefited, in the long run, by systematic deception and by the wholesale circulation of what is, to say the least, not true. I see no reason why alcohol should be made an exception to this principle.

I am, I trust, fully awake to the dangers of alcohol, to the harm which it has done in the past and continues to do in the present. If any one shall choose to find in this article a warrant for the indiscriminate and heedless use of alcoholic stimulants, the responsibility must rest with him. It is altogether foreign to my purpose to examine the wide field which a consideration of the evil alcohol may do, would open before us. There are some considerations, however, which may find a place here.

We must not forget that although alcoholic beverages may supply the place of food for healthy persons they can ordinarily do so only to a very limited extent. The exceptional cases are far too infrequent to afford the slightest warrant for substituting alcohol for accepted foods or for any portion of them, and such a course is almost absolutely certain to result in harm to the body. In this sense, there is probably rarely or never any *necessity* for the regular use of alcohol, even in a moderate degree. Therapeutically, there can be no question that many disturbances of function are favorably influenced by a reasonable use of alcohol, but even here, as good results may be frequently obtained by other means, always provided that the habit of taking medicine or considering one's self an invalid be not encouraged, which is for some people a much worse habit than a moderate indulgence in alcohol would be.

The chief reason why men all over the world take alcohol, is that they like its effects, that it makes life pleasanter, that it smooths the rough places. A few take it to drown their sorrows, to forget a trouble or a difficulty which it would doubtless be much better to meet bravely and overcome, if they could, but this is not the reason of its common use. Men like the cerebral stimulation, and the vast majority care for no further action from what they drink, and this majority can attain this effect without going further and without harm to themselves. I am well aware that very many, unfortunately, do not stop at this point. It is but too true that not merely one man's meat, but also one man's drink, is another man's poison, and some men should refrain from alcohol, just as some men should refrain from lobster, or mushrooms, or oysters, or salmon.

The temperance movement of the future, if at some time it shall have become a true temperance movement, as I yet hope it will, the temperance movement of the future will have to recognize that the field for its activity lies not in the dissemination of falsehood about what alcohol is and does, but in the control of its rational use and in the prevention of all abuse. Here is an immense and fruitful field, and were but half the energy consumed in tilling it, which has been spent in reckless denunciation and misrepresentation, the evils of intemperance would have been largely diminished. Intemperance is a terrible weed, but its roots will be found to be entangled amid many social problems of heredity, poor food, over-work, bad cooking and bad homes, all quite as important, if indeed not more important, than the question of alcohol. And as to alcohol itself, finally, there is much to do in the regulation of its quality. It has been demonstrated again and again that the harmfulness of alcoholic beverages is very commonly due to impurities which can be avoided or greatly reduced. The "wise man" in recording the ripe results of his great experience, but anticipated modern research in attributing woe, sorrow, contentions, wounds without cause, and redness of eyes, not merely to "those that tarry *long* at the wine" but also to "those that go to seek *mixed* wine."

The admixture of other so-called higher alcohols, besides the ethyl alcohol, which we have been considering in this paper, is a source of much danger. Experiments have shown thoroughly that the evil effects of ethyl alcohol in large quantities, are produced by the higher alcohols in far smaller doses. This is an interesting and very important part of the subject, but even a brief consideration of it would lead us too far.

alcohol lowers the sensibility of the skin for points, seems to rest upon one single experiment with sixty grammes of brandy.

— A physician writes to the *Medical Press*, "within the last five years, in a district embracing sixty square miles or so by the sea, I have noted the hour and the minute of no less than ninety-three demises in my own immediate practice, and every soul of them all has gone out with the tide, save four who died suddenly by fatal accident."

THE USE OF MEAT AS A REGULAR ARTICLE OF DIET IN THE NURSERY.[1]

BY CHARLES P. PUTNAM, M.D.

[THIS paper does not take into consideration the use of meat as a medicine for sick children, but is wholly confined to its use as an article of diet for children in health.]

Meat is usually given to children as a matter of routine as soon as they are able to eat it without indigestion, and the question whether it is a food suited to childhood has received no very careful consideration. Yet is seems to be generally recognized that meat has peculiar effects on the organism as compared with other kinds of food. The fact that meat has a well-established position in the diet of adults is not alone a convincing argument in favor of giving it to children, since there are other articles, such as tea and coffee which are generally believed to be good for adults, and yet almost as generally believed to be bad for children.

Dr. Clouston, of Edinburgh, says: "My experience is that children who have the most neurotic temperaments and diatheses and who show the greatest tendencies to instability of brain, are, as a rule, flesh-eaters, having a craving for animal food too often and in too great quantities. I have found, also, a large proportion of the adolescent insane had been flesh-eaters, consuming and having a craving for much animal food. My experience, too, is that it is in such boys that the habit of masturbation is most apt to be acquired, and when acquired, seems to produce such a fascination and a craving that it ruins the bodily and mental powers. I have seen a change of diet to milk, fish, and farinaceous food produce a marked improvement in regard to the nervous irritability of such children. And in regard to such children I most thoroughly agree with Dr. Keith, who in Edinburgh for many years has preached an anti flesh crusade in the bringing up of all children up to eight or ten years of age. I believe that by a proper diet and regimen, more than in any other way, we can fight against and counteract inherited neurotic tendencies in children, and tide them safely over the periods of puberty and adolescence."

My experience has not been drawn from any extended observation of such cases as Dr. Clouston describes, yet I can fully believe that his statement is a fair one. I have become convinced that children fed largely on meat are apt to have a capricious appetite, to suffer from indigestion, constipation, and also from diarrhœa, to be subject to catarrhs of the mucous membranes, and have an unstable nervous system and less resistive power in general.

As a rule the more children are allowed to take meat the more they want it, while the appetite for other kinds of food is apt to diminish.

In families where meat eating has been put off or given up for any considerable period, I have found the children to have more freedom from little and great ailments, and to be less inclined to colds and diarrhœa. In 1884 Dr. D. M. Cammann, of New York, wrote an article on "Milk Diet in Childhood."[2] After advocating milk as a food of great value, and quoting the above passage from Dr. Clouston he says: "During the past twenty-five years, in a large institution in this city, meat has been omitted from the dietary of children under eight years of age, and it must be admitted that this has been long enough to test fully the value of the diet adopted."

One of the reports of the Board says: "Past records of the institution furnish such ample proof of the value of milk and vegetable food, and the exclusion of meat from the dietary of children under eight years of age, that the medical board sees every reason to adhere for the future to the diet from which such good results have been reached in the past." He gives the dietary for the children under eight years of age, which consists of a great variety of cereals, vegetables, fruits and milk." Also of the number of deaths by years during the twenty-five years up to 1882, he reports that both the death-rate and the number of illnesses was much greater during the year 1865, when meat was added to the dietary. In a letter which he recently wrote to me he says:

"I have no new facts in addition to those mentioned in my article on milk diet, except that I have seen a number of children in private practice brought up on a diet from which meat has been omitted, until they were seven or eight years old, and the results have been favorable. I think the facts in that article speak for themselves very strongly. In the Orphan's Home a milk and vegetable diet has been tried now for twenty-five years. During all those years the death-rate has been remarkably small; gastro-intestinal troubles during the summer months have been rare. We often go through the summer without a single case of diarrhœa. This, in a large city, among 150 children, many of whom have inherited feeble constitutions from their parents, is a noteworthy fact. Then through the winter we never have many cases of bronchitis or other diseases of the lungs, and those that do have such trouble usually recover rapidly. Another fact well worth noticing is that during the year 1865, in which meat was added to the dietary, the death-rate was larger than in any previous or subsequent year, and that disturbances of the digestive organs were extremely prevalent. The literature of the subject is meagre, and I cannot refer you to any articles bearing on it, except those referred to in my paper. . . . A look at the rosy cheeks of the children would convince any one that it was possible, at least for them to be healthy without the use of meat."

But few medical writers have thought it worth while to give any arguments in favor of meat for children. It is taken for granted that meat is the proper food for every one, and that children are to have it as soon as their digestion will bear it, in any form. For example, Starr, in a book lately published on the "Diseases of the Digestive Organs in Infants and Children," simply says: "Children who have got their milk teeth may be fed a twelfthmonth, namely, up to the age of three and a half years, in the following way." His dietary contains a teacupful of beef-tea at eleven, a slice of underdone roast-beef or mutton, or a bit of roast chicken or turkey, minced as fine as possible, and potato moistened with gravy at twelve o'clock.

In this community the giving of meat seems to be on the increase. Nursing babies, whose age is still counted by months, sometimes receive a regular meal of beef-juice. Some children of two years and upwards have meat or meat extracts twice and three times a day. Certainly this is not a universal custom, but it is getting to be more and more common. The

[1] Read at the meeting of the Boston Society for Medical Observation, January 2, 1887.

[2] New York Medical Journal, March 29, 1884.

result seems to be an increasing craving for meats and other stimulating foods, and a dislike of bland foods. In many nurseries bread and milk is a forgotten mixture. Puddings, such as were the main food of children forty years ago, boiled or baked rice and sago, rennet pudding or slip, simple blanc mange, bird's nest, baked custard, and bread puddings are distasteful to many children of the present day, and often milk will not be taken unless it have a little tea or coffee in it.

Exactly what place meat holds in the nutrition different from milk, eggs, grains, and vegetables is perhaps not thoroughly understood. Certainly physiologists do not absolutely agree. The best authorities, so far as I know, say that its peculiar effects on the system are due to the abundance of the nitrogenous elements and to the presence of extractive matters which are not in themselves nutritious, but which may be called relishes, as they make other foods more tasty, and thereby more digestible. Thus Liebig's beef extract and some others are made from a liquid out of which all albumen has been precipitated. They are, therefore, not nutritious in the ordinary sense. Still they are valuable under certain circumstances, but might fairly be considered as drugs. Whether this theory satisfactorily accounts for the well-known effects of meat on the dog, whether it accounts for the condition of excitement which sometimes is observed when infants first get beef-juice, and for the craving for meat which is found in older children who have become accustomed to it, I am not prepared to say.

On the whole, the view of Roberts as given in his lectures on "Dietetics and Dyspepsia" seems to be a fair one. He classes meat with tea, coffee, and cocoa, and also with alcohol as among the stimulants. He calls those classes and races that use these articles in abundance "high fed," and says: "There are some very subtle and exceedingly curious relations between the quality of the food and the nutrition and vital habits of the body. They are profoundly difficult to understand, and yet are absolutely authentic and highly important. One would think that so long as an animal obtained his due quantity of proteids, carbohydrates, and fats, it did not matter much from what source they were obtained.

"But this is far from being the case. Experience has taught trainers that the vital habits and qualities of horses and dogs are considerably modified by the nature of their food.

"These differences are expressed in popular phrase by saying that the hunter and the coursing greyhound are 'high fed,' and the draught horses and sporting dog are 'low fed.' The same kind of distinction may be drawn in regard to the diet of different members of the human family; some are high fed and some are low fed. Speaking generally, it may be said that high feeding in the case of man, consists mainly in a liberal allowance of meat and in the systematic use of alcoholic beverages, and that low feeding consists in a diet which is mainly vegetarian and non-alcoholic.

"In drawing this contrast between high feeding and low feeding, the distinction has reference solely to the quality and not to the quantity of the food — to its comparative stimulating properties and concentration.

"If we compare, as best we may with our limited information, the general characteristics of the high fed and low fed classes and races, there is, I think, to be perceived a broad distinction between them. In regard to bodily strength and longevity the difference is inconsiderable, but in regard to mental qualities the distinction is marked. The high-fed classes and races display, on the whole, a richer vitality, more momentum and individuality of character, and a greater brain power, than their low-fed brethren; and they constitute the soil, or breeding ground, out of which eminent men chiefly arise. In calculating what may be termed the 'man value' of individuals, classes, or races, physical qualities count for relatively little. One man may be twice as strong, or twice as big, or possess twice as much muscular endurance, as another; but the difference of value scarcely goes beyond, and rarely even reaches this proportion. But the possible difference between the mental capacity of one man and another is immense, almost incalculable. If you try to assess and to compare the value or capacity of a man of eminence — whether it be eminence in art, literature, science, statesmanship, commercial enterprise, colonizing aptitude, military command, or any other outcome of brain power — with the value and capacity of an average man, you perceive at once that the proportion is not as two to one, but as ten or twenty to one, or even as a hundred or more to one.

"With regard to infants and children, we observed that they are not allowed to partake of the neccessary articles of food which form so conspicuous a part of the dietary of their elders. They are allowed neither the use of alcohol nor of tea and coffee, except gradually as they draw towards the adult age, but are fed on simple nutrients, milk, cooked cereals and more or less meat."

I have quoted thus fully from Roberts in order to be sure of making his meaning clear.

Granting the truth of his theory of high and low feeding, it seems to me to be an argument against meat for children rather than in favor of it. Childhood is certainly the age for low rather than high feeding. The breeder who takes his colt from the pasture young, and feeds him with oats, develops his muscles by work at an early age and makes a horse of him as early as possible, generally turns out to have made an inferior horse at last.

While the community is putting off the age of learning to read until eight or nine, and deploring the existence of a large and exciting literature, is it not out of place to endeavor to stimulate them with "high feeding?"

Robert's himself says, "it is important to remark that the main dietetic customs of a country are instituted for the benefit of the robust and healthy, of the sober and temperate, and those of mean or average constitution; in other words, for those who are bearing the burden of the day and fighting the battle of life. These form the great mass and bulk of the adult population, upon whose bodily and mental efficiency national progress and ascendency depend. A good many individuals, and even entire families, may not find these customs beneficial to their exceptional tendencies or weaknesses; they may even find them destructive to their health and life. Nevertheless, differences of constitution and personal idiosyncrasies have to be reckoned with; and there are frequently good, indeed paramount, reasons why individuals should, in some particular or other, depart from the general dietetic plan." I think this applies also to peculiarities of age, and he says, in speaking of the high-fed races and classes as the "soil or breeding-ground out of which eminent men chiefly arise," "It

is remarkable how often we hear of eminent men being troubled with gout, and gout is usually produced either by personal or ancestral high feeding."

A diet which tends to produce literary and scientific predominance at the cost of gout hardly commends itself as a diet for children.

Were it only claimed that meat contained nourishment in a concentrated and easily digestible form, it would still remain to be proved that this is an advantage. On the contrary, we know that for infants (not on the breast) milk combined with some, at their age, innutritive material, such as starch, is often more easily digested than milk alone. Coarse oatmeals and cracked wheat are taken by older children and adults, partly for the very purpose of giving a non-nutritive diluting material together with the digestible.

Many nations of great physical strength take no meat. We need only look at the Scotch with their oatmeal, the Egyptian sailors and the Japanese with their rice, the latter of whom perform labors that would be impossible to most meat-eating men. The same may be said of the East Indian runner.

ON THE NEUROTIC TREATMENT OF SUMMER DIARRHŒA AND CHOLERA INFANTUM.

BY ALEXANDER HARKIN, M.D., F.R.C.S., ENGLAND,
Consulting Physician, Mater Infirmorum Hospital, Belfast.

ALL experience teaches, that nations and communities increase, not so much through a preponderance of births, as by a diminished death-rate; in England, where there is, except in certain localities, an almost constant numerical relation between births and deaths and where the prevalence of a high birth-rate is often not inconsistent with an inordinate death-rate, this truth is fully recognized. In this country of large families, it has been truly said that many children appear to die that others may be born, the vacancy in the nursery is very soon supplied; but such results cannot be predicated of American households, where the deaths observe quite a different relation to the births, and where the annual increase is chiefly attributable to immigrants, nor where as in the East Indies, it is frequently found necessary to send children back to Europe in order to secure a certain amount of power and vitality in the constitution.

Although man alone is cosmopolite, yet perfect acclimatization is scarcely attainable; in the constant struggle with the elements, his constitution becomes modified in accordance with the conditions, natural and climatic, which surround him, and, although it might be concluded that the children of European parents, born in a warm climate, would be better able to bear it, than their parent; such, however, is not commonly the fact, for many languish during infancy and die before puberty.

There is also in the habits of the American people, their preference of hotel life as contrasted with the self-contained houses and homes of the British people, their almost nomadic habits, and the prevalent desire among married people to limit the numbers in families, along with the decline of muscular and the increase of nervous development, and diminished reproductive powers, sufficient reason to explain the relative deficiency there, so observable in infant life, with the enhanced value of every child to the family and to the State.

And when, with the annual return of summer, an annual hecatomb of infantile life is the result, the loss almost assumes, under those circumstances the importance of a national calamity; in the manufacturing districts of England and in the great cities of the United States, summer diarrhœa swells the death-rate to an inordinate extreme. A fatal diarrhœa is essentially an infantile disorder, and although great progress has been effected in hygiene and preventive medicine, in both hemispheres, yet so long as we are compelled to admit, with Dr. West, that fully one-half of the children born in this country perish before they reach the fifth year, or with the late Sir James Simpson, that every fourth or fifth grave dug is for a child under twelve months (which statements "mutatis mutantis" may fairly apply to the United States, we are not entitled to boast of excessive progress in civilization or sanitary science.

But great as are the resources of sanitation, they are not competent to cope alone with the epidemic causes of diarrhœa, of which an elevated temperature is the most important. With the onset of hot weather, the disease increases in frequency and fatality, and as quickly declines with its departure. Extreme heat operates by lowering and disordering the nervous mechanism of digestion. Under its influence, the systemic circulation is excited to over-activity, the circulation in the vena porta is augmented, the liver, in time, becomes enlarged, and an increased secretion of bile is the result, often followed by diarrhœa.

The cramps and spasms, the great depression of the nervous system and the powers of life, the convulsions of so frequent occurrence, and the stage of collapse which so often terminates the infant's existence, all betray the neurotic origin of the disease, and a lesion of the nervous centres.

According to Claude Bernard, the stage of collapse in cholera is referable to great irritation of the sympathetic nervous system, and, as most authorities regard cholerine, choleraic diarrhœa, cholera infantum, cholera nostras, and Asiatic cholera as one in nature, but only differing in degree, if we accept the dictum of the great physiologist in the major, we may fairly apply its teachings to the other divisions of the class. Having for many years been converted to his views on this subject, I have formulated my plan of treatment accordingly, and, knowing that the pneumogastric is the antagonist and controller of the sympathetic nerve in the abdomen, I invoke the action of that spinal nerve by applying over its sheath in the neck a rapidly acting vesicant, the liquor epispasticus of the British Pharmacopœia, with the almost uniform result, that as soon as its powerful irritation is experienced, all vomiting, purging, and cramps immediately cease, natural heat returns to the body, the patient, be he child or adult, generally falls over asleep, and finally awakes, in a few hours, quite free from danger. I apply the fluid with a camel's hair pencil from behind the ear, as far as the angle of the lower jaw, over a space three inches in length and one in breadth; a blister rises in five hours, which I dress with cotton-wool.

In the preliminary stage I enjoin absolute repose, with warmth to the surface and extremities; total abstention from mother's and cow's milk; order, when available, condensed milk, or as an alternative, arrow-root prepared with water, and the free addition thereto of port wine fairly sweetened; it is wonderful how

much wine thus administered an infant of a few months will both require and consume; and beef tea carefully freed from fat; then counter-irritation over the abdomen by poultices and sinapisms; and failing these remedies, *a small blister over the region of the liver*. This latter procedure will often be found most salutary and successful. As internal remedies, having long since discarded the old-fashioned chalk mixture and astringent tinctures, my chief reliance is placed on dilute sulphuric acid, with or without tincture of opium; if given alone, the acid may be taken after every loose motion; if with laudanum, then in regulated and specific doses; one argument for its use derived from recent speculation may be advanced, namely, that the microbes, to whose influence so much of the choleraic discharges are attributed, cannot live in an acid medium, but perish at once. Of course if milk be persisted in, as an article of food, the acid mixture will be the cause of increased griping and pain.

The simplicity and safety of my plan of treatment has been thoroughly tested by myself and many others, for several years past, and might be expected to commend itself in the cure of a class of diseases, so little amenable to ordinary medication. But personal experience in a profession noted for great caution in the acceptance of new proposals, and even open sometimes to the charge of so-called scientific scepticism is not always sufficient.

I have thought it expedient, therefore, to add to my own experience and an independent testimony to the value of the remedy from places far asunder, and witnesses wholly unknown to the writer. The first I extract from the *Lancet*, October 24, 1885, which occurs in a letter to that Journal, dated "Grantham, October 7, 1885," and signed "Harry Poole Berry, M.B., London," who states that he had read my letter on the subject in the *Lancet*, of August 16, 1884, "that he had no opportunity of trying the remedy (stimulation of the vagus) in Asiatic cholera, but, as to its being remarkably effective in English cholera, in the summer diarrhœa and vomiting, which we so frequently meet, I feel convinced after repeated trials. I have tried this external application in at least twenty cases, which were more or less severe, and occurring in patients ranging from infancy to old age. In all the cases it has been attended with marked and immediate success, the vomiting and diarrhœa being controlled almost at once, and in some of these cases I had previously tried acid and opium, catechu, chalk, and logwood. It is a method of treatment which is attended by no risk and in no way interferes with any other treatment the practitioner may see fit to carry out."

The next witness hails from Buenos Ayres, where, according to the *Lancet* of May 14 and 28, 1887, "Dr. Peacan has for many years pursued with much success the plan introduced by me for the care of Asiatic cholera, namely, the stimulation of the pneumogastric, and thus paralyzing the action of the sympathetic on the abdomen; Dr. Peacan's success in cholera treatment being a striking proof of the soundness of Dr. Harkin's views tested in a different hemisphere."

— Cholera is reported to be spreading rapidly in Tonkin. This circumstance is important, because it was from Tonkin that cholera was first imported into the military port of Toulon, leading to the serious outbreak of 1884–6.

REPORT UPON FOODS, DRUGS, AND THEIR EXAMINATION.

BY DR. B. F. DAVENPORT,
Analyst, Massachusetts State Board of Health.

COCAINE.

The great instability of cocaine is now well known, simple contact of the free alkaloid with water being sufficient to decompose it. Atropine is found to be similarly decomposed, though not so readily. Cocaine hydrochlorate should be required to be absolutely neutral, volatilize completely, dissolve clear and colorless in water, give a colorless solution with strong sulphuric acid, not reduce potassium permanganate immediately, and when heated with an excess, give off no odor of bitter almonds. Ecgonine, a decomposition product of cocaine, is devoid of anæsthetic properties, but acts as a tetanizing poison.

TEREBENE.

Terebene is the optically inactive product of the action of strong sulphuric acid upon turpentine. Dr. Tidy asserts that only the impure samples exercise any physiological action.

ARTIFICIAL QUININE.[1]

The discovery of a method of producing quinine artificially at an extremely low cost has been announced, and if confirmed, would, no doubt, be of great chemical, if not commercial interest. Considerable reticence has, however, been manifested as to the process, and, practically, all that is known is that some samples claimed to have been thus produced present the peculiarity of being contaminated by impurities corresponding in their properties to the alkaloids accompanying quinine in cinchona bark.

PULQUE AND MESCAL.

From the aloe or maguey plant, some thirty varieties of which grow wild throughout Mexico, besides pulque or Mexican beer, and mescal, the chief spirit of the country, a distillation resembling a coarse quality of gin, and very intoxicating in its character, there is produced a fine quality of brandy, known as tequila, which is highly valued on account of its purity and strength, the unfermented juice or sap direct from the plant being called hydromel, or honey juice. By the mixing or blending of these products with each other and other fluids, many alcoholic drinks are compounded. After tapping, a single plant will yield, upon an average, over a gallon of juice a day, or about one hundred and twenty gallons during the three following months, before it dies.

PROPRIETARY MEDICINES.[2]

The medical commission having charge of licensing the sale of proprietary medicines in Russia has recently reported upon a medicinal water which claimed to have effected marvellous cures, that, upon chemical analysis, it proved to be absolutely identical with the water of the Neva River, at St. Petersburgh.

TOXIC POWER OF ALCOHOLS.[3]

The alcohols due to fermentation constitute a natural chemical series, of which the formulæ go on increasing by a CH_2 molecule from ethyl alcohol C_2H_6

[1] The Pharm. Jour. and Trans., January 1, 1887.
[2] The Pharm. Jour. and Trans., January 8, 1887
[3] Dujardin-Beaumetz and Andigé. Experimental Researches on the Toxic Power of Alcohols, Paris, 1886.

O_1, through propyl and butyl to amyl alcohol $C_5H_{12}O_1$. Their toxicity increases with their ascent in the series. All the spirits in common use contain variable proportions of these different alcohols. While wine-spirits naturally contain but minute quantities of the higher alcohols, potato and grain spirits contain them in larger quantities. Experiments in chronic alcoholism made upon hogs gave the following medium toxic doses per kilogram of weight for the several alcohols, in their pure state; namely, ethylic, 8.0 grammes; propylic, 2.9; butylic, 2.0; amylic, 1.7.

If impure ferments are used, iso-alcohols are generated, of which the toxicity is greater than that of the pure alcohols. Rice and maize will, with pure ferment, produce ethyl alcohol of almost absolute purity, not even needing rectification, so minute are the higher alcohols.

HORSE-FLESH *vs* BEEF.[4]

Dr. J. Bell, of the Inland Revenue Laboratory, London, seeking for a practical method for distinguishing between horse-flesh and beef, has shown that the usual physical appearances relied upon by the inspector of slaughter-houses at Paris are not certain. He observed that the adipose tissue of the horse was of a softer and more oily nature than that of beef. Upon experiment, he found that horse-fat at 70° F. formed a clear oil, and the amount of solid fat deposited at lower temperature was comparatively small. The melting point of beef-fat varied between 110° and 116° F. The specific gravity of horse-fat at 100° was 0.9084 to .9088, while, with beef-fat, it was 0.9036 to .9040. This difference affords a positive means for distinguishing horse-flesh from beef.

INSECT-POWDER.[5]

The Dalmatian insect-powder has, for several years, been cultivated on a large scale by Dalmatians settled in certain portions of California. The employment of insect-powder by way of fumigation is exceedingly effective, particularly in closed rooms, where the dense smoke produced by it, which is not at all disagreeable to human beings, soon kills all insects, particularly those having tender or soft bodies. This method is especially valuable for the purpose of killing mosquitoes in rooms.

DRUGS USED AT ST. BARTHOLOMEW'S HOSPITAL.

The paper by Dr. W. S. Church in the Hospital Report upon its pharmacopœia and apothecary shop, has brought out interesting points as to the quantities of the various drugs consumed, and the dates of their introduction. Epsom salts is the drug used in the largest quantities. The last thirty years consumed 120¾ hundred-weights against 43¼ hundred-weights for the preceding twenty years. Taking the ordinary dose at half-an-ounce, gives 340,480 doses as dispensed in the course of the year of this drug alone. In 1836, there was 8¾ tons of linseed meal used, while, during the last ten years, it has averaged 15¾ tons. In 1837, leeches to the number of 96,300 were used, while, since 1870, they have averaged only 1,770. Bark first appeared in the pharmacopœia of 1739, although probably already used for fifty years. The average yearly consumption of quassia rose from 6 pounds in 1844, to 506 pounds between 1866 and 1875. Quinine averaged 143 ounces yearly between 1836 and 1845, while for the last ten years it has been 1,123 ounces. Potass. bromide, averaged 146 pounds between 1866 and 1875; since then, 347 pounds yearly. Potass. iodide, averaged 105 pounds between 1836 and 1845, and 463 pounds between 1876 and 1885. During the year following 1846, when Dr. Hughes Bennett wrote upon cod-liver oil, 17 gallons of it were used, while between 1876 and 1885 it has averaged 1,368 gallons. In 1842, a quarter-pound of ergot was ordered, but since 1870 it has averaged 146 pounds. In 1848, of chloroform, 17 pounds were used, but during the last ten years, 286 pounds upon the average. Of glycerine, 32 pounds were used in 1852, but now it averages 2,303 pounds a year. In December, 1875, two ounces of iodoform were ordered, and in 1884 there were 115 pounds used. In 1878, of vaseline, 20 pounds were used, but in 1885 it was 3,257 pounds, with no corresponding decrease in lard. Of this last, 1½ tons are used annually in zinc, sulphur, and white precipitate ointments.

PEPPERETTE.[6]

This material consisting of ground olive stones is much used for adulterating pepper. The microscopical appearance of its cells is not unlike the scleregenous cells found in true pepper.

OIL OF WINTERGREEN.[7]

Since the artificial production of salicylate of methyl of good uniform quality at a cost below that of natural oil of wintergreen or birch, the supply of the natural oil may soon cease to be of any commercial importance.

STROPHANTHUS.[8]

From the seeds of *strophanthus kombe*, Prof. Fraser has isolated a glucoside, which he named strophanthin, while for the *strophanthus hispidus*, Hardy and Gallois have obtained a crystalline bitter principle possessing like toxic properties which they have called strophantine. Probably other species of the plant also contain the like principle.

ANTITHERMIN.[9]

This new synthetically prepared compound recently added to the list of antipyretics has the systematic chemical name of phenylhydraginlevulinic acid, and bears a near chemical relationship to antipyrin. Antithermin has been proposed for its commercial name, and it is said to be obtained by dissolving phenylhydragin in dilute acetic acid, and adding to it a solution of levulinic acid, which gives rise to a yellow precipitate. It is obtained in well-formed crystals upon recrystallization from alcohol.

EUCALYPTUS OIL.[10]

M. Noel states that he has often found this oil to be largely adulterated with oil of turpentine.

CHINESE ANÆSTHETIC.[11]

Dr. W. Zambuth in the annual report of the Soochow Hospital mentions a substance resembling wax, but harder, and semi-transparent, which when digested in water together with a small woody excrescence made a mixture possessing well-marked anæsthetic proper-

ties. The finger held in it for some minutes did not then feel the prick of a needle. A Chinese physician described it as being the juice of the eyes of a frog. It was probably obtained by placing a frog in a jar containing flour, and irritating the animal, when it exudes a fluid which forms a paste with the flour.

JÁMBUL SEEDS.[12]

The bark and seeds of the indian plant jámbul or jámnu, have been lately represented as arresting the formation of sugar in diabetes. Experiment has shown that while a certain quantity of diastatic matter converted 44.8 per cent. of the starch employed into sugar in fifty minutes, normally, with the same materials and in the same time, but 19.6 per cent. was converted when fifteen grains of jámbul powder was also present, and only 12.6 per cent. when twenty-five grains of the seeds were present.

CORROSIVE SUBLIMATE SOLUTION.[13]

For dissolving corrosive sublimate distilled water only should be used, as by natural hard water the oxychloride is precipitated out, and in making the ordinary solution of 1 part in 1000, over 80 per cent. of the sublimate may thus be lost, and the solution contain but 1 in 5000 parts in reality. If, however, the natural carbonates of the hard water be decomposed by some acid, as say by one fluid ounce of good white wine vinegar to the gallon of water, this precipitation can be prevented.

FUSEL OIL PREVENTED.[14]

M. Gayon and Dupetit at a recent sitting of the French Academy, presented a method for preventing the secondary fermentation in the production of alcohol, to which the formation of the higher alcohols are due. It was the addition of bismuth salts to the fermenting fluid, they claimed, that thereby only the pure ethylic alcohol was generated.

ARTIFICIAL BORNEOL.

A German house have lately announced that they had succeeded in producing artificially borneol, the camphor so highly prized by the Asiatics for its odor. It would form a valuable material for perfumers, who could thus realize some novel effects, as really new odors which can be made available commercially are rarely discovered.

NATIVE WINES AND BRANDIES.[15]

An examination of native white and red wines and brandies, to ascertain how far they conformed to the requirements of the "United States Pharmacopœia," and were adapted to medical and pharmacopœial purposes has shown that they answered all the requirements except in a few instances.

INTESTINAL GASES.

Of special interest in connection with the proposed treatment of phthisis by the injection per rectum of hydrogen sulphide gas diluted with carbonic anhydride are the analyses which have been made by Prof. Planer, E. Ruge, and C. B. Hofman, of the gases naturally to be found within the intestines, and which have been published in the *Sitzungsbericht d. Wien Akad. de Wiss.*, Bd. 42 and 44, and in *Wien Med. Wochenschrift*, 1872, No. 24. They analyzed the gases resulting from flesh, vegetable, and bean diets in men, dogs and rabbits. Stated briefly, the natural gas was found to be an admixture in quite various proportions, of carbonic anhydride with hydrogen, marsh-gas, oxygen, nitrogen and hydrogen sulphide. This last was found to be usually a decomposition product formed within the large intestines, and not to be present in a larger proportion than from 1 to 2 per cent. Planer found that the presence of 10 per cent. in an injected gas, being quickly absorbed, developed symptoms of poisoning in dogs. He could not detect it in the breath, which W. Kühne claims that he himself easily did.

Hospital Practice and Clinical Memorandum.

CLINICAL NOTES ON DR. BERGEON'S TREATMENT OF CHRONIC DISEASE OF THE LUNG AND AIR PASSAGES BY MEDICATED GASEOUS ENEMATA.

BY FRANCIS P. KINNICUTT,
Physician to the St. Luke's Hospital, New York, and the New York Cancer Hospitals.

DURING the past three months, Dr. Bergeon's method of treatment of chronic disease of the lung and air passages by means of gaseous enemata, has been employed in the author's wards in St. Luke's Hospital and in his private practice, and the results carefully observed. With one exception, all of the patients thus treated, had been under observation for considerable periods of time, during which their weight, the daily amount of sputa, the temperature curves and the physical signs had been accurately noted.[1] The apparatus employed was Dr. Morel's, of Paris; either the Richfield Springs or the Sharon water, preferably the former, was used to charge the carbonic acid gas (which was freshly prepared for each enema) with sulphuretted hydrogen.

Five litres of the gas, as a rule, were injected once daily; occasionally a similar amount was injected, a second time, in the twenty-four hours. The following tables illustrates the results obtained in the individual cases in which this treatment was employed.

At the present time, the author's experience with this method of treatment has been far too limited to prevent of more than a corroboration of some of the statements which have been made by Dr. Bergeon and others, in regard to it. That it is capable of lowering the pulse, reducing the temperature, diminishing the severity and frequency of the sweats, of markedly diminishing the amount of the expectoration, of improving the appetite, in other words of greatly *ameliorating* many of the distressing symptoms of advanced phthisical disease, does not seem to admit of doubt. That it is capable of "rapidly arresting early cases of phthisis," cannot yet be affirmed from the comparatively limited experience of American physicians. From their published reports, up to the present date, it would seem that Dr. Bergeon's method had been employed by them chiefly in cases of *advanced* disease, which may justly be considered as incurable by any method of treatment. "To *cure* phthisis, treatment must be instituted before extensive destructive disin-

[1] In all of the cases of phthisis, tubercle bacilli in large numbers had been found in the sputa.

Cases.	Physical Signs on Admission.	Results after enemata for	Temperature	Weight	Appetite	Amount of sputa	Sweats	Physical signs
1 Male 33 years	General tubercular infiltration of both lungs, with cavities at both apices. Evening temperature quite constantly 102°, before treatment.	26 days	Evening range from 98.5°–100°	Gain of 4 lbs.	Improved	Reduced from 2 oz. to ½ oz.	Ceased	No appreciable change. Marked improvement in general condition
2 Female 33 years	General tubercular infiltration of both lungs, with cavities at both apices. Evening temperature before treatment, 102°+	19 days	Slightly lower range until death	No effect	Improved	Reduced in 24 hours from 5 oz. to ½ oz. without further change	Improved	Not affected Death on 23d day
3 Male 25 years	Laryngeal phthisis; extensive consolidation of upper lobe, left lung, areas of softening and cavity. Evening ranges of temperature, 101.5°–102.5.	30 days	No effect	No effect	Improved	Slightly diminished	Improved	Not affected
4 Male 18 years	Small cavity at left apex, with extensive consolidation of upper lobe of same lung. Beginning trouble at right apex. Evening ranges of temperature 101°–102°.	39 days	Normal	Gain of 8½ lbs.	Improved	Reduced from 10 oz. to 2 oz.	Ceased	Signs at right apex disappeared, with exception of slightly wavy inspiration
5 Male 39 years	Cavity at right apex, with areas of consolidation and softening throughout upper lobe, same lung. Evening range of temperature, 101°–103°.	22 days	Evening range 100°–101°	Gain of 3 lbs.	Improved	Slightly diminished.	Markedly diminished in frequency and severity	No appreciable change
6 Female 45 years	General bronchitis (chronic) emphysema and asthma.	3 days Asthmatic attack relieved completely by enema.				Markedly diminished		Disappearance of moist rales, signs of emphysema. Unaffected
7 Female 15 years	Large abscess of lower lobe of left lung. 12–16 oz. of fœtid pus by mouth daily. Little or no elevation of temperature.	20 days		Gain both before and dur'g treatm't	Always good	No effect Fœtor unaffected	Not present before treatment	Unaffected
8 Male 55 years	General bronchitis (chronic) apyretic.	18 days		No effect	Marked improvement	Markedly diminished	Not present before treatment	
9 Female 35 years	General tubercular infiltration of both lungs. Cavity at left apex. Softening at right apex. Evening range of temperature, 102°–104°.	25 days	Slightly lower range	Loss of 6½ lbs.	Improved	Reduced from 15 oz. to 10 oz	Ceased	Unaffected

tegration of lung tissues has occurred." The subjection of the diseased tissues to aseptic and anti-septic influences is the basis of the modern treatment of pulmonary tuberculosis, and rests both upon a sound pathology and upon clinical experiences. The removal to comparatively aseptic climates, is quite impossible in the case of the majority of sufferers from phthisis, and it is to these patients and in the early stage of the disease, that Dr. Bergeon's method would seem to offer possibilities, which cannot be disregarded. It will be seen from a study of the above tabulated report, that in all the cases of phthisis, the disease was far advanced. In cases 1 and 9, the last stages had been reached. In cases 4 and 5, the patients were confined to their beds before the treatment was instituted, and were rapidly failing. They are at present able to be up and out of doors, and the improvement in their general condition is most striking.

In case 5, the patient had been in the wards for six months, and although under as thorough antiseptic medication as possible, his condition has steadily grown worse.

Only a single opportunity presented itself for a trial of the efficiency of the treatment in paroxysmal asthma. The results were such as to warrant its repetition in similar cases. By a careful attention to the details of his method, as insisted upon by Dr. Bergeon, absolutely no disturbance was caused in any of the cases, with the exception of occasionally an uncomfortable feeling of abdominal distension, by the administration of the enemata.

— Dr. Pawlik, Docent in obstetrics and gynæcology at Vienna, has been named an ordinary professor at the Tscheck medical faculty of Prague.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

MEETING, January 3, 1887. DR. E. J. FORSTER in the chair.

DR. C. P. PUTNAM read a paper upon

THE USE OF MEAT AS A REGULAR ARTICLE OF DIET IN THE NURSERY.[1]

DR. FOLSOM stated that while his ideas were similar to those of the reader to a certain degree, still he felt that many cases of pale and anæmic children were better treated by a meat-diet than by medicinal tonics.

DR. E. G. CUTLER said that the dietary of a large asylum, which was the home of children of all ages, from a few months to puberty, had not been modified for a great many years, as the health-rate had been so good. Meat was given bi-weekly only.

DR. H. C. HAVEN stated that the same results were found following either too high or too low a diet, and that much of the evil that was attributed to some special diet really was due to the improper digestion of the albuminoids ingested.

DR. REYNOLDS thought it was not advisable to adopt a uniform method of feeding for all children of the age under consideration. If the members of one family profit by the food advised by the reader, the condition of their neighbors may distinctly call for tonic feeding or even for stimulants. Age is only one factor in the question. The paper records that dysentery prevailed in the New York Dispensary

[1] See page 30 of the Journal.

when animal food was added to the diet, yet how valuable a remedy has uncooked meat been in many a case of diarrhœa?

DR. C. M. GREEN said that, although he had seen the injurious effects in children of eating too much meat, he had often been puzzled to know what food to advise in certain cases in which, as often happens, the child does not take kindly to the old-time simple puddings and farinaceous preparations mentioned by the reader. A plain diet of bread and butter, and milk, becomes monotonous to many children, and some variety must be given them, or the appetite will flag. Eggs he had found to be less easily digestible by children than meat, and some children do not care for potato and other vegetables. He thought that fish was a suitable article of food not sufficiently appreciated: being much less rich in stimulating extractive matters, it was peculiarly well suited to children. He believed, however, that even beef and mutton could be given in moderation two or three times a week without ill effects, and the other days could be provided for with fish and poultry. With this variety, bread, butter, and milk, together with fresh fruit, would make up an ample diet. Some children do not care for meat, and thrive on an exclusively vegetable and farinaceous diet: he did not believe in urging such children to take meat. Each child's proper diet should be arrived at by individual experiment and observation.

DR. ROTCH remarked that so far as the ideas of Clouston and others might lead to a more careful supervision of children's diet, in avoiding excess in the proportion of meat to vegetables and milk, they were of great value, but that he was not as yet prepared to subscribe to the entire withdrawal of meat from the dietary of children who have attained their third or fourth year, as, according to his observations, not only were the children in this community not especially meat-eaters, but the very nervous disturbances which were described in the paper, were also represented in children who eat but little meat in proportion to vegetables; he also said that he had met with quite as much if not more trouble from chronic local digestive disturbance arising from excess of vegetable diet, as he had from nervous disorders arising from too much meat: he would, therefore, while allowing that children have grown up strong and vigorous where meat had been withheld, advise for the average child of three or four years, according to its development, a carefully arranged mixed diet of soups, meats, bread and butter, milk, vegetables, and at times eggs, fish and fruits, taking care to strike out from this dietary, especial articles only where the marked idiosyncrasy of the individual seemed to indicate it, and also that this variety of food should not be used so much for especial meals and days, as for different days and weeks.

DR. C. P. STRONG presented a paper upon

THE USE OF PERMANGANATE OF POTASSIUM IN AMENORRHŒA, CLINICALLY CONSIDERED.[1]

DR. SAWIN exhibited a specimen of

RUPTURED HEART AND THROMBOSIS OF THE CORONARY ARTERY,

with the following report:

A few days ago, at about 1 P. M., I was suddenly summoned to see a gentleman, sixty years of age, who had been found by his assistant sitting in an arm-chair with his arms hanging limp at his sides. He was extremely pale and almost pulseless. When I examined him he had been removed from his place of business to his home, which was in the same building, and was sitting upright in bed. The pallor of his face was marked, lips cyanotic, and he was suffering intense pain in the præcordial region. Respiration, not unusual. Pulse, 44, and very weak. Upon auscultation of chest no abnormal cardiac sounds were detected. Brandy, aromatic spirits of ammonia, and the hypodermic administration of a quarter of a grain of morphia had a favorable effect in increasing the strength and rapidity of the pulse, though the distressing pain continued unabated. It was learned from the patient, who had been conscious from the outset, that he had been subject to asthmatic attacks for eight years, and that during the past month he had experienced occasional twinges of pain in the left chest. Deodorized tincture of opium with Hoffman's anodyne internally and hot fomentations to chest, afforded no relief, although at about 4, P. M., the pulse had increased to 70 per minute, and was apparently normal in strength. The character of the pain necessitated a frequent change of position. At about 9 o'clock, after consultation with two other physicians, another hypodermic injection of morphia was administered. At 9.30 P. M., pulse showed an intermittent character and increased to 90 beats per minute. Patient very drowsy and quite comfortable. Became suddenly pulseless during an act of vomiting, and died at 11.40 P. M. Autopsy thirty-six hours after death.

DR. R. H. FITZ described the appearances of the specimen, stating that some eight ounces of clotted blood were found in the pericardial cavity. The heart was not especially altered in size or shape, but the left ventricle was somewhat dilated and the muscle was of a paler color than normal. A rent, a half-inch long, extended obliquely across the anterior wall of the left ventricle in the middle third and ended within a half-inch of the left coronary artery. The ventricular wall in this region was less than one-quarter of an inch thick and was infiltrated with blood. A flat, reddish-gray thrombus several lines in thickness was adherent to the endocardium in the lower third of the ventricle.

The left coronary artery was thickened and calcified. About a half-inch from its origin it was filled with a soft, adherent, reddish-gray thrombus a half-inch long. Beyond the place of obstruction the artery contained liquid blood. The right half of the interventricular septum, throughout its length, was dry, opaque, grayish-yellow, presenting the appearances of an ischæmic necrosis. In general, the heart gave but little evidence, on microscopical examination, of fatty degeneration. Other abnormal appearances of the specimen than those described were not seen.

[1] Publication deferred.

— Discussing the subject of the doctor's income, Dr. Paget Thurston says that the trouble is not in want of patients, but in the low rates of fees, for Dr. Thurston says that in England ten per cent. of patients pay five shillings ($1.25), ten per cent. pay 60 cents to $1.25, while eighty per cent. pay such fees as no doctor or educated gentleman can possibly live on, the average for union, club, and dispensary patients being ten to fifteen cents.

NEW HAMPSHIRE MEDICAL SOCIETY.

NINETY-SEVENTH ANNUAL MEETING, JUNE 21, 1887.

PRESIDENT'S ADDRESS. — THE GERM THEORY.

PROFESSOR FROST traced the history of the growth of the germ theory of disease, and especially the investigations of Pasteur, of whom he said: "With a naturally bright and active mind, he came to the study of fermentation after a vigorous and long-continued training in the solution of various scientific problems by careful experimentation. Many observers have worked in this field before him. Many valuable facts had been made known, but their relations to each other were not appreciated. Trodden fields are often fertile to the fresh investigator. Oftentimes, previous and distinguished laborers have but turned the soil for future investigators." The speaker gave a long account of the investigations of Pasteur and his co-laborers, and he noted their present state of advancement. He said: Many bacteria — I use the word as including the three general classes of microbes capable of causing disease: micrococci, bacilli, and spirilla — have been discovered, and their life history carefully investigated. They are studied with reference to their physical appearance, their peculiarities of growth under varying conditions, their physiological action on animals, and their relation to fermentative fluids, when placed in suitable conditions. It is reasonably certain that the micrococcus of gonorrhœa has been found. In pus, several micrococci have been identified, one of which closely resembles that of erysipelas, a disease whose parasitic origin is now clearly settled. We have, also, the bacillus anthracis, and undoubtedly that of typhoid fever. The bacillus of pneumonia, described first by Friedländer, is still under observation; more facts may be required to establish its positive agency in the causation of this disease. The bacilli of glanders, of syphilis, and of leprosy are also probably known. The causative agency of the bacillus of tuberculosis, as discovered by Koch, may well be considered as established, as may that of cholera, and perhaps that of yellow fever.

In regard to the exanthemata, there can hardly be a doubt that for each there exists a microbe as the agent of causation, although its complete identification in any case is probably lacking. Without prolonging this enumeration, I can say that there seem to be sound reasons for the belief that our knowledge in this direction will be greatly increased in the near future.

In some cases, it may be true that much larger claims have been made than are justified by the facts. It is possible that in some instances the bacteria may be present, because the conditions under which they are found are favorable to their development, and that their presence should be reckoned as a consequence, rather than as a cause of disease.

By some, who do not yet accept the germ theory of disease, the position is taken that these microbes simply add to the dangers of the malady, and do not at all act as original etiological factors. This is a claim made, especially in regard to the coccus of pneumonia.

The knowledge of the relation of putrefaction to the presence of microörganisms has led to very surprising results, especially in surgery. Many of the dangers of surgical operations can now be avoided by strict observance of means which shall prevent the admission of putrefaction bacilli to the wounded tissue, or destroy them if they have already found entrance.

In obstetrics, the use of the so-called antiseptic precautions has shown surprisingly favorable results.

Until quite recently, there has been much doubt whether many of the good results claimed for the antiseptic method were not really due to the greater care in the treatment of the patients which it required, and to the increased cleanliness included in the process.

A more thorough study of the various agents claimed as antiseptics shows that some of the former failures in the antiseptic treatment were rather due to agents used than to the theory on which they were employed, as they were experimentally found not to be true germicides.

The relationship of conditions of filth to these organisms is an important study. Certain diseases, such as typhoid fever and diphtheria, are quite generally regarded among us as due almost entirely or solely to conditions of uncleanliness, that is, if we consider the replies made to the questions of the Board of Health of our State as indicative of the general opinion. There is no doubt that, particularly as respects the bacilli of these diseases, states of filth are favorable to their development outside the human body. Very likely, also, so-called unsanitary conditions tend to produce in the human body a favorable soil for the reproduction of these organisms, but their presence is certainly one of the essential factors in the causation of the disease.

Increasing knowledge of these organisms is continually extending the field of preventive medicine, and is thus leading to a more intelligent use of the agencies which it employs.

The question arises whether the methods of treatment by therapeutic agencies have as yet advanced to meet the requirements of enlarged views as respects the pathology of these diseases. We feel sure that they have not, but the progress will come sooner or later. The eager avidity with which any new plan of treatment, professedly based on these more recent views in pathology, is seized upon by the profession, is evidenced by the great demand for, and the extensive use of, the apparatus and medicaments required in the employment of gaseous enemata in cases of consumption, which almost amounts to a craze.

While it is best to have minds ready to be convinced on sufficient evidence, it is well not to be carried too far by the statements of early and enthusiastic explorers in these fields.

ADDRESS IN OBSTETRICS. — BREECH-PRESENTATIONS.

DR. CHILDS. Have the patient on left side, near edge of bed, with back to operator. Have thighs of patient flexed upon body moderately, and with firm bedding beneath. Have right supported by knee, as far as may be above its mate. Now, immediately on escape of body, shoulders, and arms, grasping feet with right hand, carry child around between legs, upon and parellel to abdomen of mother, making gentle, but increasing traction. The head will be delivered instantly generally, always under the conditions under consideration. There should not be an instant's delay between the delivery of body and the manœuvre, and the movement should be performed with boldness and considerable traction.

Why does this plan succeed, and why does the opposite fail? First, why does the opposite fail? When the head descends upon the lower outlet, we

have, practically, a slit in a firm, resisting texture. This opening has a diameter of four-and-one-half inches. To be drawn through this, we have the head with an ovoid form, the short diameter being three-and-one-half-inches, the long diameter being five-and-one-fourth inches. Now the whole matter of delivering the head rests upon bringing this short diameter into the canal of four-and-one-half inches. Now the head is a cylindroid, with its long diameter across the outlet. To its middle is attached a swivel, the neck uniting thereto the body. Now by traction, as directed, on the child's foot, we draw the head along in a line nearly parallel with its long axis, and thus draw the one end of the cylindroid over and above the pubic bone, allowing the other end to drop into and through the slit, and the whole head, by its lesser diameter, escapes with the utmost facility, as would a well-lubricated egg.

Judging from my own experience this situation is not sufficiently comprehended; and the manipulation is not performed with sufficient promptness and positiveness.

Remark the ovoid form of the fœtus and of all its successfully presenting parts; delivery is facilitated by having the curvatures of the fœtus correspond to the curvatures of the canal. These principles are practically recognized everywhere, in all the reproductive efforts of nature, both initial or terminal.

THE FORCEPS

is an instrument first for the mother, second for child. It is the remedy for exhaustive labor cases, and for those that could not be completed by natural or manual efforts. It never should be employed to abridge the average labor. The time, limit and occasion for the use of forceps cannot always be readily determined. But there is such a time, limit and occasion, and they should be diligently, carefully and conscientiously sought. There is a tendency to abuse the use of the forceps. The doctor said he had employed forceps for one in every sixty-six cases.

The rest of the paper was occupied in the consideration of hæmorrhage and puerperal convulsions.

The paper excited lively discussion, particularly in regard to the use of the forceps.

DR. PARSONS said that he should take more liberty in their use than the paper recommended; that he does not believe that they will produce laceration if used properly; that women could be delivered with less injury to the soft parts by the use of forceps than to let them take the natural course; that he has used forceps for the purpose of expediting labor for his own convenience.

DR. HILL suggested that there was less objection to the use of forceps if traction was made only during pains. The perineum should not be supported. Let the parts accommodate themselves to the pressure coming upon them; make the curve at the proper time; and do not pull straight forward with violence, but slowly and gently.

DR. STACKPOLE said that in skilful hands the use of forceps was attended with little danger but great advantage. In unskilful hands they are very dangerous.

DR. DOUGLAS, of New York, said he was surprised that forceps are not used in the country more generally than was indicated by the writer of the paper. Much can be done by gently and firmly helping nature dilate the parts; and at the proper time when instruments can properly be used with safety and can help the work, they should be used. In his practice he used them in about a third of his cases.

DR. NICHOLS said that when in the intelligent judgment of the physician there have been a sufficient number of pains and sufficient expenditure of force to have delivered the child, and it is not delivered, it is his duty to apply the forceps. There is not so much danger of rupturing the perineum with forceps, intelligently applied, as there is by waiting until the perineum is completely exhausted.

DR. WHITTIER said that where the curvature of the pelvis was not sufficient, the sooner forceps are applied the better. Another point: If, when we deliver the head with the forceps, the handles lie upon the abdomen, we shall have less trouble about rupturing the perineum.

There was also considerable discussion about retained placenta in abortion, several speakers suggesting that in cases of only two or three months it should not be extracted. In convulsions, Dr. Hill approved of chloral. Give your chloral either by mouth, rectal injection, or subcutaneous injection, until you have controlled the cutaneous sensibility, which is best shown by the resistance the patient offers. He gave one patient two drams of chloral by subcutaneous injection.

DR. GROSS said he did not think the stomach was an absorbing organ during convulsions, and medicines swallowed are not absorbed, but generally thrown up.

DR. WHITTIER condemned bleeding in convulsions. The patient needs the blood to help her recovery. If the pulse runs up to 140 or 150, give veratrum viride in doses of ten, fifteen, or twenty drops, until the pulse comes down to 80 or 95.

DIPHTHERIA.

DR. MORSE gave the history of the epidemic at New Market, in 1885 and 1886.

DR. CONN. In the time of epidemics of diphtheria and those of a kindred nature we shall be obliged to rely upon prevention rather than cure. Wherever epidemics occur of a contagious, infectious, malignant nature, there will always be mortality attending a certain number of cases. We must rely on prevention. Stop the disease before it commences.

DR. DOUGLAS. In the treatment of diphtheria let your medicines be given very often.

DR. WHITTIER. I do not make any direct local applications. I use tincture chloride of iron in large doses and frequently; practically saturate the system with it. I believe that, either combined or alternated with aromatic spirits of ammonia, being a very pleasant preparation of ammonia, is the best treatment you can adopt. In one year, out of thirty-six cases of diphtheria in which the throat was covered by the parchment patch, I lost none. Local applications are good to clear the throat for the time being of accumulated matter. Subsulphide of iron puckers the patches and causes them to fall off.

DR. HILL. Too much importance should not be attached to the contagiousness of diphtheria. I do not think it is as contagious as most people do. The common opinion occasions a great deal of alarm and sometimes causes neighbors to stay away when the family are suffering from want of assistance.

LACERATION OF THE PERINEUM.

DR. PERKINS gave a summary of the views of eminent authorities as to the causes and prevention of laceration.

DR. WHITTIER described in detail the operation for closing a laceration of the perineum as practised by Dr. Goodell, of Philadelphia and Dr. T. Addis Emmet of New York. He disapproved of the one, two or three stitch operation.

DR. PATTEE gave a report on therapeutics, and then spoke of

THE FUTURE OF MEDICINE

as follows: It seems to me that only two methods offer us much encouragement in a search for real remedies. First, the old experimental one by trial of drugs which is altogether too slow and uncertain for the present age. Second, by investigating more thoroughly the initial vital and chemical changes, which, in all probability always precede the grosser tissue changes. Much doubtless may be learned by studying disease in the lower animals and plants, but whence the remedy shall come is altogether too problematic at present. But it seems to me that experience renders it likely that a search among vegetable infusions and tinctures is a vain one. Possibly some of the various vegetable as well as animal ferments, generally known under the name of micrococci and bacteria, most of which, however, are merely the embryonic stages of protozoa and protophyta, injected into the cellular tissue, into the blood, or even into the cavities and viscera themselves may be followed by results little thought of. These organisms usually show great repuguance to associating with other forms, thus resembling the infectious diseases, and I know of no more effectual means of arresting the development of certain forms without radically changing the menstruum than by adding some other. Moreover, in their modes of development and general behavior as well as physical characteristics they closely resemble those found in the infectious diseases, it not being an unusual occurrence to find the counterpart to all these latter, including the noted comma bacillus, in vegetable infusions, thus indicating that they may, like the entozoa, have other hosts than the human body. From thousands of careful observations on the different parasitic forms, I think there can be no doubt that their non-microscopic products are just as effectual in including their peculiar vital activities, as the individual bacilli themselves. And although we individually may never witness its realization, the hope is not an unreasonable one, that this Society before celebrating its second centennial, may see the time when all acute inflammatory as well as contagious and epidemic diseases, shall be as effectually stripped of their terror as are anthrax and variola at the present day.

CALOMEL, SALICIN, ANTIPYRIN, ANTIFEBRIN AND SILICATE OF BISMUTH,

were discussed by DR. NICHOLS.

DR. CUTLER reported several operations of ovariotomy, and a number of cases of hernia. DR. SMITH gave a history of ovariotomy. DR. LEONARD read a paper on "The Confidence of the Public in Non-professional Prescriptions. Dr. Sanborn read one on "Homœopathy."

June 22d. Officers elected for the ensuing year: Dr. S. W. Roberts, President; Dr. S. C. Whittier, Vice-President; Dr. G. P. Conn, Secretary; Dr. Daniel S. Adams, Treasurer; Executive Committee: Drs. C. R. Walker, George D. Towne, John R. Kimball.

SIXTEENTH CONGRESS OF GERMAN SURGEONS.[1]

THE Sixteenth Congress of German Surgeons met in Berlin during the Easter vacation under the presidency of Prof. v. Langenbeck, of Halle. Prof. Billroth, of Vienna, and Sir Spencer Wells, of London, were elected honorary members. Prof. v. Bergmann, of Berlin, was elected president for the next year. Among the numerous papers read which were worthy of notice was one by Dr. Lange, of New York.

THE ACTION OF IODOFORM

was the subject of an article by DR. DE REUYTER, of Berlin. It has been claimed that iodoform has no antiseptic power. The author could even at the last Congress have reported that iodoform solution has a strong antiseptic action. It, however, as he himself has seen, acts but slightly on bacteria outside of the body, and for this object alone he uses none at all. For such purposes any other covering powder would serve the same purpose. The use of iodoform in the treatment of wounds had given him the following experience. When we make open wounds in animals by cutting out a piece of skin, inoculate the place with pathogenic organisms, and then strew the wound with iodoform powder, some bacilli, for instance that of anthrax and the desquamative septic matter will not be influenced thereby. All these animals die in a few days after the inoculation and the fact is plain that no secretion has taken place and that the iodoform has laid a long time undecomposed on the wound.

If one conducts his observations with wounds which are pocket-shaped, he finds that those animals which were inoculated with pathogenic microörganisms and were strewed with iodoform, live longer than those which have been subject to the same inoculation without the application of iodoform. In the first class of cases one could see that the iodoform had in the greatest part disappeared. This would lead to the decision that the activity of iodoform does not begin till the decomposition has commenced. We must now by analogy reason how this iodoform would act in the practice from its action here related. He had poured a large amount of pus into a dialysator and protected it from further infection. A quantity of iodoform was put in this vessel and the same placed in a cupboard, kept at the temperature of the body, to brew. On the first day no production of decomposition of the iodoform showed themselves; on the third day, however, it was determined that the decomposition of the iodoform had commenced. In the dialysator could be found a noticeably iodoform combination.

The question was, what had decomposed the iodoform, the pus or substances produced from it.

To prove this, sterilized blood serum was put in the dialysator and iodoform added in excess. For weeks no decomposition of the iodoform showed itself. After the staphylococcus pyogenes aureus and the strepcococcus were put into the blood serum decomposition took place in two days. Then the microör-

[1] Specially reported for the JOURNAL.

ganisms themselves first begin the decomposition of iodoform. The bad odor by which the pus culture is usually accompanied was absent.

The fact presented itself that the ptomaine which, as is well known, determine the odor of the pus, brought the iodoform product out of the iodoform, that is, decomposed it. The author brought by distillation after the method of Briegor to obtain the ptomaine. If a few drops of ptomaine were placed to iodoform, iodoform combinasions took place, which could be freed by nitric acid. If one brings a solution of iodoform in alcohol, in contact with culture fluids, it shows no influence on the bacteria. The author had sought further to bring alcoholic ether into the body to determine whether the transfer of iodoform was only superficial. He found that if one placed an alcoholic ether solution of iodoform on one side of the diaphragm of a rabbit, a decided iodine reaction is to be noticed. This, however, is not the case where simple ether solution of iodoform is used.

These investigations go to prove that iodoform makes the bacteria and ptomaines harmless, and prevents a general infection, when it cannot always prevent or control completely the local infection. Iodoform in solution of alcohol and water when added to the culture fluid inhibits the growth of the parasites at once or at least in a few days. For solutions of iodoform ether is the most convenient vehicle, to obtain a superficial action, and ether and alcohol solutions also disinfect the region, thereabout. As the most active the author had found a very fine granular powder. He showed two tubercular culture fluids to which iodoform solution had been added, 1-400, and no farther development of the bacilli took place. The use of iodoform in tamponades of the rectum, or in mouth wounds shows its greatest activity, which goes to strengthen the opinion that ptomaines which are most richly deposited in these protected places, are combined directly with iodoform. He now showed some interesting experiments. He took iodoform powder and poured a few drops of a ptomaine to it. On adding a few drops of hyponitrous acid an evident iodoform reaction showed itself, a proof of the decomposition of the iodoform. When, however, he took common water and placed iodoform powder and hyponitrous acid to it the iodoform remained undecomposed. He considers iodoform a good antiseptic and believes that the more the chemical peculiarities of this substance are studied the greater number of advantages it will be found to possess.

Dr. v. Tischendorf, of Leipsic, reported a case of

ENTEROSTOMY FOR CONGENITAL ATRESIA OF THE ILIUM.

He presented the specimen which had been brought to him on the sixth day of life for treatment. The doctor thought he had a case of atresia of the colon to treat, as this is sometimes congenital. Laparotomy showed an atresia of the ilium 25 cm. above the cœcum. The child only lived fourteen days after the operation. He did not vomit any more but died from general weakness.

— A recent estimate shows that about one-fourth of the population of New York, Boston, and London receive free treatment at the medical clinics; in Philadelphia one-fifth, and in Liverpool over one-half the population.

Recent Literature.

A Treatise on Diseases of the Skin, etc. By T. McCall Anderson, M.D. Philadelphia: P. Blakiston, Son & Co. 1887.

The qualifications of Dr. Anderson from experience and training, to write a treatise upon diseases of the skin are well known, and the result is a textbook of more than average excellence. The framework of the book is represented by the teachings of Hebra and the Vienna school as supplemented and modified by the personal experience of the author, and many prescriptions and tables of differential diagnosis are given, rendering the work a useful guide to both student and practitioner. G. H. T.

Practical Lessons in Nursing. Maternity, Infancy, Childhood; Hygiene of Pregnancy; Nursing and Weaning of Infants; The Care of Children in Health and Disease. Adapted especially to the use of Mothers or those intrusted with the bringing up of Infants and Children, and Training-Schools for Nurses, as an Aid to the Teaching of the Nursing of Women and Children. By John M. Keating, M.D. Philadelphia: J. B. Lippincott Co. 1887.

This is one of a series of small volumes on practical lessons in nursing. The title describes the contents, and it only remains to say that the subjects are treated intelligently, judiciously and clearly.

Cancer Massif du Foie. Par M. le Dr. A. Gilbert. 8vo. pp. 85. Paris: 1886.

This is the title of a treatise, just received, wherein is exhaustively discussed a form of cancer of the liver, which the author maintains, apparently with success, is entitled to the name he gives it, not only on account of the great size attained by the diseased organ, but for other peculiarities worthy of special consideration. It is, he declares, not a secondary affection but a primitive disease, consisting of a uniform neoplastic mass not to be confounded with secondary forms that are made up of separate nodules or other irregularities.

Large as the organ becomes it always retains its natural shape, its smooth surface, with little or no change in color. Its whole substance appears to be converted into a uniformly homogenous, softened or lardaceous mass.

In its evolution massive cancer is generally rapidly progressive, becoming immense in a very short time. Without its interfering greatly with the stomach or other digestive organs, emaciation and debility come on with great rapidity. In general the disease lasts but a few months only; and may, if very severe, terminate in a few weeks. It usually ends in exhaustion and prolonged coma.

Space forbid a more particular enumeration of the peculiarities of this form of disease as set forth by Dr. Gilbert. Therein he has made a valuable contribution to science, and it is gratifying to learn, from the preface, that he will ere long, in connection with an able elder associate, publish an extended work on the general subject of diseases of the liver.

We may add, however, that any one interested in these matters may find it worth while to examine the record of a case reported to the Boston Society for Medical Improvement and published, with illustration and discussion thereon, in this Journal, August 12, 1869, p. 19. That case corresponds most wonderfully, in symptoms, progress, and pathological details, with those described by Dr. Gilbert. C.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 14, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

STATE PROPHYLAXIS OF SYPHILIS.

THE French Academy has recently listened to a report on the public prophylaxis of syphilis from a Committee, of which the venerable Ricord was the President, and Bergeron, Le Roy de Mericourt, Leon Lefort, Leon Colin, and Alfred Fournier the other members. The "notorious insufficiency" of the present measures to protect against syphilis led the Academy to appoint the Committee to inquire what reforms or innovations it is necessary to introduce for public protection, and to prepare a draft of a report upon the subject, to be presented to the civil authorities. The Committee reported through Fournier, and its recommendations are not only interesting, as showing the condition of affairs and the growth of public sentiment in Paris and France, but are instructive for the people of other countries.

This Committee enumerates certain propositions which constitute a basis for public prophylaxis:

(1) That prostitution creates a public danger by the venereal contagion that it disseminates among the population.

(2) That it is indispensable that prostitution should be regulated, and, if possible, repressed by public authority, in the double point of view of hygiene and morality.

(3) That the system of free, that is to say, unregulated, prostitution is disastrous to the public health.

(4) That *public provocation*, which is the only form of exterior manifestation by which prostitution can be legally attacked, ought to be combatted and repressed under its divers forms.

Provocation upon the streets has greatly increased of late years in Paris, as have also the shops which nominally sell perfumery, men's gloves, photographs, etc., but which are but shields of prostitution. Other less known, but equally dangerous, forms of provocation are those which radiate about the schools and colleges, where veritable bureaus of females are organized, and recruit a special *clientèle* among the students; the breweries with female waiters, which are simply disguised houses of prostitution, and the wine-shops, worse than the last, which attack, particularly, the working class and the army. The Committee desire that public provocation, as the fertile source of contagion, shall be considered a crime; that provocation by means just mentioned, wine-shops, etc., shall also be regarded as a crime to be legally suppressed. The punishment appropriate to the crime the medical commission does not undertake to specify, but only to suggest that public safety demands the periodical medical inspection of females found guilty of public provocation, and the confinement of those diseased in a special sanitary asylum. This proposition differs from the present system in two particulars: it substitutes for the present arbitrary police system one which has respect for individual rights for a basis, and must be carried out with due legal formalities; for confinement in prison it substitutes treatment in a special hospital.

Under the present system, the police directs everything with a high hand. It establishes the crime by the report of its agents, and nothing more; it judges the crime by its chief of the *bureau des mœurs*, and this, too, without chance for defence; it "inscribes" the girl considered guilty; it punishes all infractions of its own regulations; physicians chosen by the police establish the fact of disease, and have charge of the diseased in prison. Here is an exorbitant discretionary power like to nothing else, contrary to justice and modern ideas. While expressing the opinion that the police officials have always acted for the public good, the Committee did not hesitate to say that the system does not meet the public approval.

For such arbitrary procedure the Committee proposes to substitute a regulation like the following: The inscription of any girl guilty of provocation upon the public streets can never be made, except by a court of justice after cross-examination and opportunity for defence. Certain changes in details in regard to the medical examination of the inscribed prostitutes are suggested which it is unnecessary to repeat here, but certain reforms in the hospital treatment are of more immediate interest. The number of beds devoted to the treatment of venereal maladies is at present notoriously insufficient. The commission desire that hospital accommodations shall be increased by the creation of new special hospitals. The most useful thing to diminish the number of syphilitic contaminations is to send to the hospital every patient affected with contagious lesions, thus removing even the possibility of transmitting the disease. To confine syphilis in its contagious forms in hospitals, is to render it inoffensive. It is then necessary that the number of beds allotted to the treatment of syphilis shall be equal to or even greater than the requests for admission. The great expense attendant upon such a scheme, should not stand in the way of carrying it out, for the present expense would constitute an economy for the future, in diminishing the number of contaminated subjects. The drugs proper for the treatment of venereal diseases, should be dispensed

gratuitously at all hospitals, special and general. Gratuitous consultations with the free distribution of medicine, should be given at the special sanitary asylum intended for the treatment of diseased prostitutes.

One of the best means of combatting syphilis is to teach the rising generation of medical students better than is done to-day, to recognize the great malady under its divers forms, to treat and cure it. The greater number of students take up practice with only the most superficial and rudimentary knowledge of venereal affections and of syphilis in particular, and as a consequence errors in practice are numerous; the chancre is confounded with this or that, the mucous patch or other specific manifestation is unrecognized, syphilitic children are confided to healthy nurses, or inversely, syphilis is considered cured after some weeks of treatment, patients are permitted to marry too early while still capable of infection, errors which tend to spread the disease and which might have been avoided by a more complete education. The Commission therefore devoted much study to the means necessary to develop proper knowledge among the younger generation of medical men. The measures advised are the opening of all venereal services to students of proper advancement; to demand of every aspirant for a degree, before the deposit of his thesis, evidence of three months' study in a venereal service; to determine by the *concours* the appointment of all the medical staff destined to treat syphilitics and to carry out the sanitary regulations previously mentioned.

In the army, especially, syphilitic contaminations are lamentably frequent, and the committee recommended a series of measures as follows:

(1) To institute in the army a series of *conferences* with the object of enlightening soldiers upon venereal affections in general, and upon the dangers of syphilis in particular, upon the benefit of a scientific treatment and the necessity of prolonged treatment.

The lectures should be given by the military surgeons of each corps; they should be annual and should by preference take place soon after the enrollment of the young recruits. A like conference should be given to the reserves the day following their assembling, and in support of the need of such care of the reserve it is stated that it is impossible to count the number of reservists who contract syphilis during the twenty-eight days that they pass away from home.

The committee believe firmly that these lectures can have the best results in enlightening an immense number of young men who take their places with the colors in a state of ignorance, almost absolute, concerning venereal affections and their consequences. Little by little can be extended through the regiments sanitary notions which will do more in the way of prophylaxis than the most strenous regulations. And as the great majority of Frenchmen are subject to military duty, it follows that at the end of some years healthy notions will have penetrated through the community.

(2) To obtain from a soldier who has recently contracted syphilis, the name of the woman from whom he has contracted the disease. These names should be addressed to the Prefect of Police, who should return to the military authorities the result of the examination. Such a course would reveal many centres of contamination. It is frequent in the army to see many men of the same corps, contaminated from the same source. One military surgeon communicated three cases in which eight, ten and twenty-two men had been infected by the same female.

(3) To formally forbid the presence of soldiers in the wine and liquor shops.

(4) To remove everything like punishment from the military prophylaxis of syphilis.

(5) To suppress the custom of consulting the surgeon in public and make the consultation and examination strictly private. At present the military surgeon sees his patients in the presence of others of the same corps, and the publicity induces many men to conceal their malady as long as possible.

(6) To institute a special service of police about the great camps.

(7) To maintain a system of externe service, by which soldiers shall have continuous treatment for their disease after the severe symptoms which sent them to the hospital have passed.

As a last point of prophylaxis, it is proposed to make an attempt to do something for the protection of nurses from infection from nurslings. At present, when for any reason the mother does not nurse her own infant, and hires a wet-nurse, it is customary to require the nurse to submit to a medical examination, to establish chiefly her freedom from syphilis. The nurse is equally liable to be infected from the nursling, but no nurse is in a position to demand guarantees from her employers of their health and that of their child. If it is a possible thing to accomplish, society ought to afford the nurse the protection she cannot demand for herself. It is scarcely to be hoped that such reciprocal guarantees can be generally demanded, since most contracts between nurse and family are strictly private in their nature, and, for the most part, the nurse is content without any guarantee. But many of the wet-nurses of Paris are obtained through intelligence-offices, which are strictly under police control. For nurses obtained through the medium of these offices, it is possible to obtain a certain protection by the enactment of such a regulation as the following: No one is permitted to take a wet-nurs from any intelligence-office, except upon the presentation of a medical certificate guaranteeing the nurse against infection, which can be transmitted by the nursling, and the certificate should read somewhat as follows: "I, the undersigned, doctor of medicine, etc., certify that to the best of my knowledge and belief, the parents of the infant, X., who have been under my medical care since ———, are not infected with any inheritable malady which can be transmitted to the nurse suckling the said infant."

The Commission do not believe that any physician would falsely sign such a certificate. Syphilitic families would then be obliged to seek nurses outside of the intelligence-offices, and some would be deterred from such search, and there is room to hope that the greater number of nurses would be attracted by the protection given by the medical certificate, and perhaps, after a time, other nurses outside the offices would be led to demand similar guarantees. The effect of such a regulation would not entirely abolish the infection of nurses by nurslings, but it would diminish the number of such unfortunate infections, and is preferable to leaving the matter without any attempt at regulation.

TREATMENT OF INFANTILE DYSPEPSIA BY LACTIC ACID. THE CAUSATION OF THE GREENISH DISCHARGES WHICH CHARACTERIZE THIS AFFECTION.

HAYEM, in charge of the Children's Department of St. Antoine Hospital, in a communication recently made to the Academy of Medicine,[1] claims signal success in the treatment of gastro-intestinal irritations of infants, especially such as are attended with green discharges, by lactic acid. He employs a two per cent. solution, of which a teaspoonful is given to the infant a quarter-of-an-hour after nursing. From five to eight such doses, representing about half-a-gramme (or seven-and-a-half grains) of pure lactic acid are administered during the twenty-four hours. The effects of this treatment, it is said, rapidly show themselves. The vomiting (where vomiting exists) ceases almost immediately, the diarrhœa lessens in frequency and amount, and the discharges soon take on their natural yellowish hue.

Hayem was led to adopt an acid treatment in these cases from having frequently tested the vomited and fæcal matters, and found them neutral or alkaline. In these discharges, moreover, he detected the constant presence of a strange microbe, clustering in masses. This microbe he has been able to isolate and cultivate in gelatine-peptone, and, by experimental researches undertaken with his interne, Lesage, he thinks that he has conclusively shown that these masses of bacteria produce the greenish matter by a sort of excretion. This microbe, moreover, can only live and multiply in an alkaline medium, and the etiological conditions which bring about the gastro-intestinal dyspepsia of infants, by modifying the secretions of the alimentary canal, make it a fit habitat for the microbe, which now becomes the principal factor in the graver accidents which characterize the disease. These micro-organisms, it has been found, soon perish in an acid medium.

Hayem first tried dilute hydrochloric acid with some success, but soon found that lactic gives the best results. This acid, he says, acts in two ways: it combats the dyspeptic condition by giving the stomach the degree of acidity required for healthy digestion, and it sterilizes the germs of the bacillus, thus effectually antidoting the pernicious effects of the latter on the digestive tube. Lactic acid is, moreover, pleasant and easy of administration.

The contagiousness of this gastro-intestinal affection with green discharges is a natural corollary from the fact, real or assumed, of its bacillary origin. This contagiousness, Hayem affirms, is proved beyond the possibility of a doubt by clinical experience, and when once a case of the kind enters the wards of the children's hospitals, an epidemic of the disease is sure to follow.

Recently, at a meeting of the Academy (May 31st)[2] Damaschino claimed priority over Hayem in the discovery of the microbe supposed to be the causal agent in the diarrhœa with green discharges in young children, and produced micro-photographs which he presented three years ago to the Society of Biology, and which he affirmed to be representations of the same microbe described by Hayem as causative of the disease in question. These bacilli are of characteristic forms and dimensions, and constitute an important morphological element of the stools of young diarrhœic patients. They are the more numerous, the more severe the affection, and in three grave cases of green diarrhœa, they presented the appearance of pure cultures in the microscopic preparations. In the fresh state, they are animated by rapid movements. These bacilli disappear as the disease diminishes in intensity, and the discharges take on their natural yellowish hue.

Hayem, in replying to the communication of Damaschino, did not deny the value of the discovery of the latter investigator, of which he (Hayem) was ignorant at the time of the presentation of his paper, only Damaschino had not proved any causal relation between the masses of rod-like forms which he had found in the green discharges of infantile diarrhœa and the disease. This proof, Hayem claimed, had been furnished by his interne, Lesage, who had isolated and cultivated the specific microbe, and, by introducing the pure products of his cultures into the digestive canal of animals, had reproduced the disease, with the identical green discharges. The report of these interesting experiments Hayem has promised to give at an early day.

THE BOSTON MEDICAL LIBRARY ASSOCIATION.

THE JOURNAL always takes pleasure in referring to the Medical Library, as it regards it as one of the chief powers at work in Boston for the elevation of the profession. The last report of its enterprising librarian shows that the remarkable growth of the library continues and that its capacity for usefulness has greatly increased. In the last two years the total number of volumes has increased to 17,124, and the pamphlets from 12,289 to 14,832. The library is

[1] Bull. Gen. de Thér., May 30, 1887.

[2] Semaine Medicale, June 2, 1887.

evidently to maintain its fulness in periodicals as several hundred volumes which will serve to complete some of the most valuable series, have been obtained by the librarian in England and France and will be received during the coming year. The value of the principal periodicals of the world is increasing each year as the War Department publishes its annual volume of the Index Catalogue. While the Boston Library is very far indeed from containing all the periodicals indexed by that wonderful catalogue, it is a constant surprise to see the very large files of journals it places at the command of the student.

The library, books, pamphlets and periodicals, has been catalogued and the catalogue is to be kept even with the occasions. It is a matter of surprise that the library has never received any gifts of money as such, but notwithstanding, it owns its building, and has a small fund, which generous donors might well increase.

There is one drawback to the usefulness of the library. It is hardly possible to find a quiet spot for reading where one is not liable to be disturbed by the inevitable noise inseparable from so busy a place. The directory for nurses which is located in the same building, and of which the assistant librarian is the registrar, introduces many non-medical persons into the building, and somewhat destroys the quiet which ought to reign in a library. A larger building and one better adapted to the present and prospective wants of the library association, is a necessity that must soon be supplied. It would be a graceful act for some one to show appreciation of the profession by enabling the library to acquire a proper building in the near future.

MEDICAL NOTES.

— There have been several new cases of yellow fever at Key West recently, and two deaths. Up to July 10th the record shows, total cases, 83; deaths, 27; sick, 33; discharged well, 23.

A temporary refuge station is being established by the Marine-Hospital Service at Egmont Key, where ten days' detention will be required; also disinfection of baggage. The health officer of Philadelphia has ordered all vessels from infected ports, including at present Key West, to report at the United States Quarantine Station at Delaware Breakwater before coming into the Philadelphia Quarantine Station on the Delaware River. The health officer at Camden, N. J., has issued a similar order.

— The Medico-Legal Society of New York, at its May Session, upon the recommendation of its Executive Committee, unanimously authorized two prizes to be announced. First, of $100.00; second, of $50.00, for the best paper on any Medico-Legal subject, to be awarded by a committee to be selected by the President of that body.

— Professor Esmarch, of Kiel, who years ago married the aunt of the Crown Prince of Germany, and who is said not to have had the warmest of welcomes by the august family into which he married, has at last been knighted. Gossips further affirm that the love-match between the Princess Henrietta and the young professor has been productive of far more domestic happiness than has fallen to the lot of most of the other Hohenzollerns.

— The following passage occurs in a very pretentious paper on the "Progress of Science from 1836 to 1886," by Grant Allen, in the *June Fortnightly*: "Anæsthetics are almost entirely a growth of our half-century: chloroform was first employed in operations by Simpson, in 1847, and the use of other similar agents is still more recent." One is at first inclined to think that surely such a misstatement must be intentional, but a little reflection shows that it would be absurd to make such a blunder on purpose, so we must ascribe it to ignorance, and offer the editor of the *Fortnightly* our sympathy. If he has not yet paid for the article, we think he would be justified in making a deduction.

— The *Detroit Tribune* recently published a highly picturesque account of the way in which a female physician fathomed the fraud of a young man who had been simulating hæmorrhage from the lungs, in order to secure sympathy from his associates at a fashionable boarding-house, and cash from his relatives. In one of these pretended attacks, a female physician resident in the house was quickly called. "Her practised eye," says the account, "quickly took in the situation of things. As she approached him, she saw the red stains on the handkerchief and the linen of the young man, and she also saw that the blood-corpuscles, although generically allied to the prostrate patient, were distinctively different, inasmuch as they belonged to the species with four legs, instead of two. She astonished the self-imposed nurses by asking the patient where he got the lamb's blood which he had just spit out of his mouth?" If the "practised eye" can do all this without a microscope, what cannot its owner accomplish with the aid of a good lens?

NEW YORK.

— The effect of the recent hot weather was quickly shown in the mortality lists of the city. The reports of the Bureau of Vital Statistics show that during the week ending July 2d, there were 1,024 deaths, against 788, the week before. The greatest increase was, of course, among children under five years of age; from diarrhœal diseases; and a considerable number of deaths were also due to direct insolation. During the week there were very few cases of contagious diseases reported, excepting as regards diphtheria, of which there were 132 cases.

— During the same week there were 520 deaths reported in Brooklyn, a higher mortality than that city has known for years. More than half of the entire number were in young children, 352, and 190 of these were due to diarrhœal diseases. Ten physicians have recently been appointed to inspect the tenement districts of Brooklyn.

— During the six months ending June 30th, there were reported in the city of New York 19,312 deaths, and 15,442 births; an increase of 1,731 deaths and 439 births as compared with the figures of the first six months of 1886. Since the first of January, 1887, there have been reported over 1,000 deaths from diphtheria, an average of 43 per week. One great cause of the prevalence of this disease is no doubt the almost complete disregard of the section of the Sanitary Code, which requires that the bodies of persons dying from contagious diseases shall be buried within twenty-four hours after death, and that the funeral must be private, and instances were known to the health authorities in which wakes were held over children who died of diphtheria. One of these was in a large apartment-house, and is said to have been attended by the servants of many of the families living in it.

— Mayor Hewitt has appointed Dr. Joseph D. Bryant, Professor of Anatomy and Associate Professor of Orthopædic Surgery, at Bellevue Hospital Medical College, Health Commissioner to succeed the late Dr. Woolsey Johnson. He was formerly a sanitary inspector in the health department, and is at present surgeon-general of the State; having been appointed to that position by Governor Cleveland, and re-appointed by Governor Hill.

— At a meeting of the Board of Education, held July 5th, the committee on course of study and school books, presented a report in favor of the introduction of manual training into the public schools, the consideration of which, however, was deferred until September. The Committee says that "it is a matter of deep regret, and even of apprehension, that a large proportion of our young people are growing up with a positive distaste for manual labor. On the other hand, the introduction of manual training into many of the schools and higher educational institutions of the country, has already begun to exert an influence toward bringing about a better state of things." It is estimated that the expense of introducing and maintaining manual training, in accordance with the plans recommended by the committee, will be $128,500 for the first year, and $89,500 for each year afterward.

— Twenty-one families were made ill, though none of the cases of sickness seem to have been very serious, on the 4th of July, by ice cream procured from a well-known and reliable confectioner on Sixth Avenue. It was ascertained that all these families were supplied from a particular freezing, and Dr. Cyrus Edson, of the Board of Health was requested to make a thorough examination of the matter and also of the confectioner's establishment and processes of making ice-cream. Dr. Edson is of the opinion that the cases of sickness were due to tyrotoxicon generated in the milk by decomposition after the cream was made, and has given a sample of the cream to Mr. E. N. Martin, of the School of Mines, Columbia College, for analysis.

—A decision just handed down by the Court of Appeals, in the case of the people against Charles Kibler, of Buffalo, is regarded as of considerable importance. The defendant was indicted for selling milk adulterated with water, and at the trial it was proved that the milk sold did not reach the standard required by the statute. The defence was that the seller had bought the milk from a wholesale dealer, and that as he supposed it to be pure and acted in good faith, he could not be convicted. The question before the Court of Appeals was, whether a person could be convicted of a criminal charge when he believed he was doing nothing wrong, and by the affirmation of the judgment of the General Term of the Supreme Court, the higher court has established the law of the State to be that the question of knowledge and intent is no defence to a charge of violation of a statute, and that a person who sells milk or butter must know just what he is selling.

— Keepers James McHugh and Patrick Cleary, of City Insane Asylum on Ward's Island, who were recently charged by a coroner's jury with the responsibility of the death of one of the inmates, by the name of Farrish, have been indicted by the Grand Jury for manslaughter in the first degree.

Miscellany.

CORROSIVE SUBLIMATE IN TYPHOID FEVER.

DR. GLÄSER, of Hamburgh, after a communication by Gruffenberger in the *Berliner klinische Wochenschrift* for 1885, setting forth the beneficial results of corrosive sublimate in typhoid fever, resolved to make a trial of it. According to his experience, corrosive sublimate does not possess the virtues ascribed to it, such as immediately lowering the temperature, causing the tongue to become soft, etc. Dr. Gläser carried out a comparison of similar cases: the one series without corrosive sublimate, the other series treated with it. By studying the curves of the cases, twenty-three in all, in which the pulse and temperature are given, one can observe at a glance that the administration of corrosive sublimate never reduced the temperature and rate of pulse immediately. This failure was deemed more striking when two similar cases were examined presenting precisely similar courses, the one with and the other without corrosive sublimate. According to Dr. Gläser, the drug does not in the least diminish the mortality. Another point of note in this paper is the estimation of the percentage of corrosive sublimate in the blood, which is infinitely too small for it to exert any influence whatever on any micro-organism that might be present and cause the disease. Its beneficial influence, therefore, if any, cannot be attributed to this particular effect.— *Practitioner, June,* 1887.

OPERATIONS ON THE BRAIN.

ACCORDING to the London correspondent of the *Philadelphia Medical Times*, Mr. Victor Horsley has published statistics of the first ten cases in which he has operated on the brain. The first operation was

performed in May 25, 1886, the last on December 17, 1886. Two of the patients have died; one six months after operation, from recurrence of the tumor; the other nineteen hours after the operation, which was performed as a last resort in a hopeless case of widespread paralysis due to cerebellar tumor. As to the wound, immediate union took place in every case, excepting of course the patient who died in nineteen hours. Mr. Horsley is thus fully justified in claiming that the operation of exposing and removing considerable portions of the brain is not to be ranked among the "dangerous" procedures of surgery. Before operating, morphine is administered, and it is found necessary to use very great care in the subsequent inhalation of chloroform, as dangerously deep narcosis may easily be induced, especially in children; the object in giving the morphine is to produce contraction of the cerebral arterioles in order to diminish hæmorrhage. Special care is taken to fashion the scalp flap (for the old crucial incision is abandoned) so as to preserve either the temporal or the occipital arteries, and the periosteum is reflected along with the cutaneous structures. The bone is first of all attacked with the trephine, and the aperture in it is enlarged with a circular saw driven by a "surgical engine" (dentist's). After excising the tumor, cyst or cicatrix the flap is replaced and completely sewn up, except for one inch at the most dependent part, where excess of fluid can drain away, but a drainage-tube is not used. "I am more than ever convinced," says Mr. Horsley, "that the arachnoid, like the peritoneal cavity, may be trusted to absorb excess of fluid." Strict Listerism is observed for the first four or five days, or until the wound is healed.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 2, 1887.

Deaths reported 2,622: under five years of age 1372; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1,467, consumption 241, lung diseases 123, diarrhœal diseases 738, diphtheria and croup 109, measles 29, scarlet fever 21, typhoid fever 18, malarial fever 18, cerebro-spinal meningitis 11, whooping-cough 11, erysipelas eight, puerperal fever four. From scarlet fever New York 12, Brooklyn five, Somerville two, Boston and Pittsburgh one each. From typhoid fever, District of Columbia and Pittsburgh four each, New York three, Brooklyn two, Boston, New Orleans, Milwaukee, Nashville and Lawrence one each. From malarial fever, New York six, New Orleans four, Baltimore and District of Columbia three each, Richmond two. From cerebro-spinal meningitis, New Orleans and Milwaukee two each, New York, Boston, District of Columbia, Nashville and Salem one each. From whooping-cough, Boston four, New York and Pittsburgh two each, Brooklyn, Richmond, and Lawrence one each. From erysipelas, New York four, Brooklyn two, District of Columbia and Milwaukee one each. From puerperal fever, Pittsburgh three, Baltimore one.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending June 18th, the death-rate was 18.4. Deaths reported 3,252: infants under one year of age 772; acute diseases of the respiratory organs (London,) 213, measles 226, whooping-cough 132, diarrhœa 49, scarlet fever 41, diphtheria 26.

The death-rates ranged from 12.2 in Derby to 28.5 in Manchester; Birmingham 13.4; Hull 19.6; Leeds 18.9; Leicester 14.6; Liverpool 20.7; London 17.2; Nottingham 16.1; Sheffield 21.1; Sunderland 19.7.

In Edinburgh 18.4; Glasgow 21.6; Dublin 26.7.

The meteorological record for the week ending July 2, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JUNE 25, 1887, TO JULY 8, 1887.

SUTHERLAND, CHARLES, colonel and surgeon. Granted one month's leave of absence, with permission to apply for an extension of one month. S. O. 126, Division of the Atlantic, June 23, 1887.

SMITH, A. K., lieutenant colonel and surgeon. Will be relieved from duty at West Point, N. Y., on September 30, 1887, instead of on August 28, 1887. S. O. 144, A. G. O., June 23, 1887.

MCKEE, J. C., major and surgeon. Granted three days' leave. S. O. 149, A. G. O., June 29, 1887.

ALDEN, C. H., major and surgeon. Leave of absence extended to include September 29, 1887. S. O. 144, A. G. O., June 23, 1887.

TREMAINE, WM. S., major and surgeon. Ordered for examination by Army Retiring Board, at Governors' Island, New York Harbor. S. O. 151, A. G. O., July 1, 1887.

SKINNER, J. O., captain and assistant surgeon. Granted leave of absence for four months, on surgeon's certificate of disability. S. O. 151, A. G. O., July 1, 1887.

HARRIS, H. S. T., first lieutenant and assistant surgeon. Will be relieved from duty at Fort Ringgold, Tex., upon the return of Assistant Surgeon W. T. Carter, and will then report to commanding officer at Fort McIntosh, Tex., for duty. S. O. 73, Department of Texas, June 27, 1887.

BEALL, GEORGE T., captain and medical storekeeper. Granted four months leave of absence. S. O. 150, A. G. O., June 30, 1887.

CHERBOUNIER, A. V., captain and medical storekeeper. Directed to take charge of office and perform duties of acting assistant medical purveyor, in St. Louis, Mo., during absence on leave of Captain George T. Beall, medical storekeeper, now performing those duties. S. O 150, A. G. O., June 30, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE TWO WEEKS ENDING JULY 9, 1887.

DEANE, C. W., passed assistant surgeon. Ordered to the Naval Rendezvous, San Francisco, Cal.

HARRIS, H. N. T., assistant surgeon. Ordered to the Naval Hospital, Mare Island, Cal.

GORGAS, A. C., medical director. Remain on present duty until December 31, 1887.

CLEBORNE, C. J., medical inspector. Remain on present duty until December 31, 1887.

MACKEY, BENJ. F., surgeon. Remain on present duty until December 31, 1887.

BROWNE, J. MILLS, medical director. Will remain on present duty as Member of Retiring Board until June 30, 1888.

DEAN, RICHARD C., medical director. Will remain on present duty as Member of Retiring Board, until June 30, 1888.

HUDSON, A., medical inspector. Detached from the "Trenton," and wait orders.

SCOFIELD, W. K., medical inspector. Ordered to relieve Medical Inspector Hudson on the "Trenton."

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING JULY 2, 1887.

ARMSTRONG, S. T., passed assistant surgeon. Relieved from duty at Marine Hospital, Memphis, Tenn.; ordered to Marine Hospital, New York, N. Y., June 27, 1887.

PECKHAM, C. T., passed assistant surgeon. Relieved from duty at Marine Hospital, Wilmington, N. C.; ordered to Marine Hospital, Memphis, Tenn., June 27, 1887.

GLENNAN, A. H., passed assistant surgeon. Ordered to Revenue Cutter "Crawford," for temporary duty, June 30, 1887.

BROOKS, S. D., assistant surgeon. Ordered to examination for promotion, June 27, 1887. Relieved from duty at Evansville, Ind.; ordered to Marine Hospital at Wilmington, N. C., June 27, 1887.

CORRECTION OF CAMBRIDGE COMMENCEMENT PROGRAMME.

We are requested by the Secretary of the Medical Faculty of Harvard University to insert the following:

By mistake the name of Wm. H. Prescott was sent instead of William Abbott Phillips, Ph. B., for honorable mention on the Commencement Programme at Cambridge, for a thesis entitled "Fracture of the Patella."

ANALYSIS OF ONE HUNDRED AND FORTY-ONE CASES OF PREGNANCY WITH REFERENCE TO THE DIAGNOSTIC VALUE OF THE BLUE COLOR OF THE VAGINA.[1]

BY JOHN W. FARLOW, M.D.

In looking over the varied opinions of medical authorities on this subject, it has seemed to me that there must be some good reason for this diversity of opinion. To me, a very possible explanation is that the vulva and vagina are not sufficiently examined. In the ordinary bimanual examination to determine the existence of pregnancy, the color of the vagina is not inquired into, and, particularly where the patient is examined on the side, it is easy to see how the color of the vagina might escape observation entirely. If a sufficient number of cases are carefully examined, we shall soon be in a position to make up our minds as to the value of the blue color of the vagina, especially when found on the anterior wall.

I have looked over my records, and tabulated one hundred and forty-one cases of pregnancy, which I examined with regard to this point. In this table, I have not included a number of cases where the diagnosis was doubtful, but only those where a birth or miscarriage subsequently took place, or where the future history left no doubt in the matter.

The inspection of the vulva and vagina was made in all cases before determining the increased size of the uterus. I divided the cases into three classes: (1) Those where there was no blue color of the vaginal orifice or urethra. (2) Those where the blue color was slightly marked, and not limited to the anterior vaginal wall or around the urethra. (3) Those where the color was markedly blue or violet, or where even a less marked blue was limited to the anterior vaginal wall or the urethra.

The following table shows in how large a proportion of cases, even in the early months, a blue color, at least, suggestive, if not characteristic, was present. In half the number, it was regarded as characteristic, and of the remaining seventy-one, one-half were suggestive. Thirty-six cases are regarded as showing no blue tinge.

TABLE OF 141 CASES OF PREGNANCY.

How Long Pregnant.	No Blue Color.	Suggestive.	Characteristic.	Total.
6 weeks	1	1	..	2
2 months	11	10	1	22
2½ "	5	3	..	8
3 "	12	5	11	28
3½ "	1	1	1	3
4 "	1	8	10	19
4½ "	3	4	7	14
5 "	..	1	15	16
5½ "	..	1	4	5
6 "	1	..	11	12
6½ "	..	..	1	1
7 "	1	..	3	4
8 "	..	1	6	7
	36	35	70	141

Let us now examine a little in detail the column marked "no blue color," and see if we can make out any reason for its non-appearance. The case where the color was absent at seven months was a patient with chronic eczema of the vulva, and the entrance of the vagina, as well as the whole vulva, was intensely red, and the skin was glazed and cracked. The case where there was no blueness at six months was one of secondary syphilis, and was soon followed by a miscarriage. At four-and-one-half months are three cases, where there is no blue color. One was a case of eczema, where the vulva and vaginal orifice were much excoriated and pigmented. The prevailing color was quite red. Another case had previously had three miscarriages, and two months before I saw her, that is, when she was two-and-one-half months pregnant, she had a hæmorrhage from the uterus. The third patient had had gonorrhœa a few months before. At four months, is one case of absence of blue color. The introitus was red, and the cervix and body were harder than is usually the case, and at first I was inclined to think it might not be pregnancy, but a possible fibroid.

The patient who had no blue color at three-and-one-half months was apparently about to miscarry, as she was having pains, the os was dilating, and there was some hæmorrhage.

At three months there are twelve cases. In one, there was a slight hæmorrhage two weeks before. One had gonorrhœa. One became pregnant while nursing a baby thirteen months old. The pelvis, particularly Douglas's pouch, was tender. In another, the perineum was torn into the rectum, and the introitus was a firm cicatrix. The broad ligaments were very hard. In the other eight cases, nothing unusual is noted.

Of the five cases at two-and-one-half months, two had flowed several times before I saw them.

At two months, we have eleven cases. In four the uterus was retroverted. In one the clitoris and labia were large, wrinkled, and pigmented, suggesting masturbation. In two, an eczema caused a red and excoriated vulva and introitus. In another, the labia minora were bluish, but not the vagina. In still another, an erosion of the cervix existed, with marked leucorrhœa and a red vagina. I have no details as to a possible cause in the other two cases.

The case of absence at six weeks was a patient who had weaned her baby the week before.

Let us now turn to the column marked "suggestive." The one case at eight months was suffering from secondary syphilis. At five-and-one-half months is a case without special history. The one at five months became pregnant when her baby was six months old. One at four-and-one-half months became pregnant when her baby was three months old. One at four months had syphilis, and had had several miscarriages. Among the suggestive cases of a still earlier period, I find one case of bloody leucorrhœa and one of cervical polyp. The rest were apparently normal.

If we now return to the "no blue color" column, and sum up what has been noted, we shall find four cases of eczema, one of syphilis, four of recent hæmorrhage, two of gonorrhœa, two pregnant while nursing young babies, four retroverted uteri, one extensive cicatrix of perineum, one possible masturbation, with resulting pigmentation, one eroded cervix — eighteen cases in all, or one-half the cases in this column.

In the "suggestive" column, we find two cases of syphilis, one of recent hæmorrhage, two nursing young

[1] Read before the Section of Obstetrics and Gynæcology of the Suffolk District Medical Society, March 16, 1887.

babies, one cervical polyp, recently removed — six in all. In the two columns together, are three cases of syphilis, five of recent hæmorrhage, and four of nursing young babies.

Can these conditions be considered as influencing in any way the color of the vagina? The blueness is due to hypertrophy of the venous plexuses of the vagina, and is not a pigmentation. It seems reasonable to infer that whatever affects the blood-supply of the vagina, or changes the character of its mucous membrane, might have a marked influence on the color of these bloodvessels, as seen through the vaginal mucous membrane. A uterine hæmorrhage, polyp, or threatened miscarriage might cause a decided change in the amount of blood in the pelvic bloodvessels. I have certainly seen a well-marked blue color disappear after a threatened miscarriage, where there was considerable hæmorrhage, to reappear later. For the same reason, we should not expect the color in cases of bleeding fibroid in an unimpregnated uterus, and, in case of pregnancy, might not the color appear later than usual?

In regard to syphilis, it is so common a disease that I do not know whether it has any causative effect in this instance or not. It certainly modifies the color of all eruptions on skin or mucous membrane, and it may have had a similar effect in my cases.

Eczema existed in four cases, and I think it very conceivable that the eczematous color should so predominate as to mask the blue color. In the same way, a gonorrhœa or vaginitis might obscure the color.

Whether retroversion has any effect, I do not feel that I can draw any conclusion from four cases. The circulation in a displaced uterus is certainly disturbed, but whether this extends to the veins of the vagina I have never seen stated.

In regard to those who nursed young babes, I do not think it is of importance, for I have seen the blue color well marked in a number of such cases.

The conditions in the other cases noted I shall not have anything further to say about.

Now the question arises: does a marked or so-called characteristic blue color exist where there is no pregnancy, and how often? I have notes of three cases where the color was almost characteristic, and one where I deemed it *quite* so. The first had a blue color universally distributed over the introitus. The second had a blue tinge near the urethra. This was a case of fistula in ano. The next had a blue sheen over the whole introitus, and the last case showed a marked blue color on and at the side of the urethra. This patient had a long, hard cervix, and suffered from dysmenorrhœa. I dilated her cervix a month ago, with great relief to the menstrual pain. I saw her yesterday, and found that the blue color had extended up the urethra and anterior vaginal wall. The uterus was perceptibly enlarged, and she has had some nausea in the morning. Menstruation is expected in a day or two, and possibly she is pregnant. I shall watch for the blue color with interest.[2]

These notes are taken from the records of about two thousand gynæcological cases, and when we compare the table of cases of pregnancy with the facts as I have stated them in regard to the non-pregnant cases, to my mind it leaves no doubt of the value of this diagnostic sign. Among these cases, there have been, of course, fibroids, ovarian tumors, large ovaries, uterine displacements of all kinds; in fact, the cases that are usually found among so large a number of cases, but in only the four which I have detailed was the color in the least characteristic.

I have also had occasion to notice its absence in many cases of women who supposed themselves pregnant, but who were not so. Where I have used the word blue or markedly blue in this paper, wine-color or violet, would, in some cases, be more appropriate. I have examined for it with the patient on her back, and with my fingers I have separated the folds of vagina, so as to get a good view, particularly of the anterior wall of the vagina, and in some cases I have used the speculum. In private practice, and under many circumstances, it is a mode of observation that cannot be undertaken. My attention was first particularly directed to this point by Dr. J. R. Chadwick, seven years ago. I have endeavored, in my gynæcological clinic, to see if my cases threw any light on the subject.

[2] I have seen this patient since the above was written. She menstruated without pain three days after I saw her before. The blue is not quite as marked as it was just before menstruation.

SUPPLEMENTARY OVARIES.[1]

BY JOHN HOMANS, 2d, M.D.

THE short paper which I am about to read this evening does not contain much original work or present any very startling matter for your consideration, but it is written to call the attention of the section to a few facts which it seems have not received the consideration that they merit.

These facts may seem rather small and insignificant, but my excuse for presenting them to you is, that attention to minuteness and carefulness of detail is thought of more and more importance as medical science advances.

In the Richmond and Louisville *Medical Journal* for 1875, Dr. Goodman collected and published 27 cases of double ovariotomy by various native and foreign operators, in 10 of which the operation had no influence whatsoever on menstruation; in one the flow was increased and in one the function was irregularly performed.

Nearly forty per cent., therefore, of these cases, were not much affected by the removal of both ovaries. Since the publication of this paper, however, this high proportion of non-affected cases has not been maintained. As there have been 117 other cases collected, of which only 8 still menstruated after the operation, this makes a total of 144 accessible cases of double ovariotomy, of which 18 or nearly twelve per cent. were uninfluenced by the operation. The explanation of this apparent anomaly, may, I think, be found in the fact that many of these patients had supplementary ovaries.

Winkels' work on the "Pathology of the Female Sexual organs," gives a good figure, but no description of a supplementary ovary, and Waldeyer in his classical work on the "*Eierstock u. Ei*," refers, it is true, to small bodies occurring in the neighborhood of the ovary, which he calls "supra-ovarian bodies," but Dr. Hermann Beigel was the first to give an accurate description of the supplementary ovary in an article in

[1] Read before the Section of Obstetrics and Gynæcology of the Suffolk District Medical Society, March 16, 1887.

the *Wiener Med. Wochens.*, for 1877. In a series of 350 autopsies on persons of all ages, but chiefly adults, Beigel found eight cases of supplementary ovaries. In number they varied from one to three, but as many as six have been noted by another observer. They were either pediculated or were found lying free in the broad ligament. When pediculated they invariably are situated at the line of reflection of the peritonæum. The true ovary really lying more than half outside the peritoneal cavity. The pedicle is a true one, that is, it is composed of a coarse net-work of connective tissue without any follicular structure, and there is a sharp line of demarkation between the pedicle and the tissue, both of the normal and supplementary ovary. Microscopical examination of the latter shows normal ovarian tissue, in fact, gives a complete likeness in miniature of an ovary. They vary in size from the traditional millet seed up to that of a pea.

The fact that when pediculated they always are found attached to the line of reflection of the peritonæum, offers an explanation for their occurrence. Just at this point, according to the biologists, ciliated epithelium is found in all mammalia, and here also, Waldeyer says, the limits of the germinal epithelium (the Keim-epithel of the German embryologists) are not clearly defined and this epithelium is of variable dimensions. During the developement of the ovary a pocket in the irregular outline of the germinal epithelium becomes occluded and is cut off from what might be called the parent organ and thus, the anatomical requirements being all met, becomes the seat of a supplementary ovary.

Now in the majority of the before mentioned cases, in which spaying did not produce the menopause, the menses were only temporarily arrested, gradually returning more or less nearly to the condition existing before operation. These cases it seems to me may be fairly explained by the existence of supplementary ovaries which have slowly enlarged under the benign influence of the reparative forces of nature, and gradually taken on more and more of the functions of the normal organs. It is then, I think, evident that the surgeon who is about to operate for a bleeding fibroid or for the relief of "ovarian neuralgia" or of mental or moral symptoms, cannot be sure that he has extirpated *all* the primal cause of the distressing or alarming symptoms he is seeking to alleviate, when he has simply removed both ovaries. I do not intend to discuss the advisability of Battey's or Tait's operation, or the relation between ovulation and menstruation, but granting the two premises that, first, the former are proper and justifiable surgical procedures, and second, that the ovaries are active factors in menstruation.

I would in closing call attention to the fact that of the cases operated upon in accordance with these premises, from four to six per cent. cannot be in the least benefited because of a distinct anatomical reason.

A REPORT OF TEN CASES OF PHTHISIS TREATED WITH GASEOUS ENEMATA.

BY A. GASTON ROETH, M.D., BOSTON.

A VAST field for clinical investigation and research was opened to us when Claude Bernard showed in 1857[1] the action of toxic and medicinal agents when administered per rectum.

When this great teacher demonstrated the fact that hydrogen sulphide, H_2S, could be safely injected into the veins and rectum, afterwards to be eliminated by the lungs, he was followed by Bergeon and Cornil whose practical experiments, covering a number of years, were reported to the French Academy of Medicine in 1886.

The reports of these gentlemen well established the fact that hydrogen sulphide, when carried into the economy by means of carbon dioxide CO_2, played a most important rôle in its effects upon pulmonary disease of acute and chronic character, and especially under conditions where pulmonary suppuration and co-existing septicæmia were prominent and alarming symptoms.

These latter experiments were but the forerunners of many others calculated to place the treatment of pulmonary diseases, and especially of tubercular phthisis, by the gaseous enemata upon a sound and practical basis. How far they have succeeded I shall endeavor to show from the following ten cases, and as few statistics have as yet been offered the profession, although the system has been in use for some time at the Hospital of the University of Philadelphia, German Hospital and Home for Consumptives, I feel at liberty to give here the result of my observations in such shape that you may formulate your own conclusions.

The cases now under consideration were taken from the Boston Dispensary, where a careful diagnosis was primarily made by Dr. John Dixwell, their local lesions well defined, each patient carefully weighed and his general condition recorded. Their sputa were stained and examined, the number of bacilli found classified in accordance with Gaffky's scale, now accepted by bacteriologists as a standard of measurement for this bacillus. The same ground was gone over at the end of one month's treatment. I desire here to express my grateful thanks to Dr. E. W. Cushing, whose kindness in re-examining the specimens of sputa, both at the beginning and end of the treatment, leaves no shadow of doubt as to the correctness of each particular case classified.

It will be noticed that in spite of the bad hygienic surroundings in which these patients lived, every one apparently without exception destitute, yet, notwithstanding the unfavorable atmospheric conditions, the prevailing winds, easterly and cold, and all orthodox advice and medication having been suspended, and a steady and perceptible amelioration has been ob-

[1] Leçons sur les substances toxiques and medicamenteuses.

served in each and every instance. So far as the practical administration of the gas, its mode of preparation or quantity used is concerned, I have little to add to what has already appeared in the many articles heretofore published, both in the secular and medical journals, with the exception that my preference in natural sulphur waters is for the Ypsilanti spring of Michigan, as this water contains 21.0786 cubic inches per gallon of sulphuretted hydrogen, both liquid and free, more than any other that I know of; my next choice being the Blue Lick of Virginia, which contains 10 per cent. No bad effects have been noted, an overdose of the gas seems impossible, and no intestinal colic was produced when the quantity used was slowly injected. The time most favorable for the two daily enemata was found to be before meals, morning and afternoon.

CASE I. Julia N., aged thirty-one. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 110 lbs.	Weight 114½ lbs.
Temp. 100°.	Temp. normal.
Pulse 120.	Pulse 78.
Respiration ratio .26.	Respiration ratio normal.
Expectoration copious, and muco-purulent.	Expectoration, none.
Night sweats.	No night sweats.
Appetite poor.	Appetite good.
Bacilli, Gaffky's scale No. 2.	Bacilli, Gaffky's scale No. 1.
Cavity right infra clavicular space and right apex.	Broncho vesicular respiration decreased.

She states that she does not cough once during the night, spits but once in a while, is feeling splendid, better than for years. Sleeps all night; eats well.

CASE II. James P., aged forty-two. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 116½ lbs.	Weight 118½ lbs.
Temp. 98°.	Temp. 98°.
Pulse 86.	Pulse 86.
Respiration ratio 19.	Respiration ratio normal.
Expectoration copious, yellow and white.	Expectoration normal.
No night sweats.	No night sweats.
Appetite fair only.	Appetite good.
Bacilli, Gaffky's scale No. 1.	Bacilli, Gaffky's scale No. 1.
Cavity left apex front and back.	Small area of sibilant râles over left apex on expiration.
First stage phthisis.	

He states that he has improved daily. His appetite is good; sometimes spits but once a day. Feels a great deal stronger and better; sleeps well; cough less distressing, and does not keep him awake now. Is able to work at his trade of carpenter again.

CASE III. Arthur M., aged thirty-six. Hereditary.

At Beginning of Treatment.	
Weight 114 lbs.	Night sweats.
Temp. 99°.	Appetite fair.
Pulse 93.	Bacilli, Gaffky's scale No. 10.
Respiration ratio 15.	Cavity right apex and middle lobe.
Expectoration copious, hæmoptysis.	

After eight days' treatment he stated that he was much better. Sleeps better and never coughed less since he has been sick. He feels quite encouraged. Feels no more pain under his right nipple. At this period he ceased coming for treatment.

CASE IV. Richard M., aged thirty-seven. Hereditary.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 94½ lbs.	Weight 94½ lbs.
Temp. 99°.	Temp. 99°.
Pulse 72.	Pulse 72.
Respiration ratio 24.	Respiration ratio normal.
Expectoration copious and hæmoptysis.	No hæmoptysis and expectoration decreased.
Night sweats.	No night sweats.
Appetite bad.	Appetite good.
Bacilli, Gaffky's scale No. 2.	Bacilli, Gaffky's scale No. 1.
Cavities both apices, third stage.	Physical signs not much changed.

He tells me that he feels like a different man altogether. Does not feel so sore through his chest and has no steady pains as formerly. Is not spitting nearly so much, and has no night sweats now. He sleeps better. He does not cough at all during the night.

CASE V. John M., aged forty-six. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 130½ lbs.	Weight 132½ lbs.
Temp. 99°.	Temp. normal.
Pulse 103.	Pulse 74.
Respiration ratio 29.	Respiration ratio normal.
Expectoration copious, brown and green, no hæmoptysis.	Expectoration normal.
Night sweats and chills.	No night sweats.
Appetite fair.	Appetite good.
Bacilli, Gaffky's scale No. 1.	Bacilli, Gaffky's scale No. 1.
Recurrent pneumonia, right apex crumples, left solidified.	Right apex does not crumple, left respiration partially restored.
Anæmia and debility.	No râles, general condition improved.

He states that he feels better every time he comes. Does not spit at all. No night sweats; appetite good. Is a great deal stronger and can do many things now which he could not do a month ago. He now feels as if he could work at his trade of marble polisher. His breathing is as good as it was twenty years ago.

CASE VI. James R., aged twenty-six. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 125 lbs.	Weight 125½ lbs.
Temp. 99.1°	Temp. 99°.
Pulse 130.	Pulse 96.
Respiration ratio 21.	Respiration ratio normal.
Expectoration copious, yellow.	Expectoration slight.
Night sweats.	No night sweats.
Appetite poor.	Appetite good.
Bacilli, Gaffky's scale No. 2.	Bacilli, Gaffky's scale No. 1.
Cavities both lungs, moist râles, broncophony, wasting.	Small improvement in condition of lungs.

He states that his appetite is much improved. Feels considerably better; spits and coughs less. Sleeps all night; has no night sweats at all. Thinks he is improving under the treatment.

CASE VII. Louis S., aged forty-seven. Hereditary.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 134 lbs.	Weight 132 lbs.
Temp. 99°.	Temp. 98°.
Pulse 70.	Pulse 72.
Respiration ratio 20.	Respiration ratio normal.
Expectoration copious and hæmoptysis.	Expectoration decreased.
No night sweats.	No night sweats.
Appetite fair.	Appetite good.
Bacilli, Gaffky's scale No. 3.	Bacilli, Gaffky's scale No.— Improvement.
Cavity left apex back.	

He says that he feels altogether better and stronger. Does not cough or spit so much; says that if it were not for the bad winds, that he would gain flesh, as his appetite is improved.

CASE VIII. Daniel S., aged twenty-five. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 102½ lbs.	Weight 102½ lbs.
Temp. 99.2°.	Temp. normal.
Pulse 122.	Pulse 96.
Respiration ratio 27.	Respiration ratio normal.
Expectoration copious.	Expectoration decreased.
Night sweats.	No night sweats.
Appetite poor.	Appetite good.
Bacilli, Gaffky's scale No. 1.	Bacilli, Gaffky's scale No.—
Cavity right apex.	Condition of lung improved.

He states that the night sweats have entirely ceased, that he coughs only in the morning. Sleeps a great deal better; spits only in the morning, and much less, and that his appetite is better. Feels stronger.

CASE IX. Michael M., aged twenty-one. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 73½ lbs.	Weight 72½ lbs.
Temp. 99.1°.	Temp. normal.
Pulse 114.	Pulse 104.
Respiration ratio 21.	Respiration ratio normal.
Expectoration copious, yellow.	Expectoration less and lighter color.
No night sweats.	No night sweats.
Appetite fair only.	Appetite good.
Bacilli, Gaffky's scale No. 1.	Bacilli, Gaffky's scale No. —.
Cavity right apex and right base, has had phthisis six years. His breath is most offensive, and suggestive of gangrene of the lungs.	Left lung good, right about as before, but nothing more. General condition better. The fetor of his breath has materially decreased.

He says that he feels better and that his friends say that he is looking much better. Sleeps well and coughs less.

CASE X. Patrick McG., aged thirty-seven. No family history.

At Beginning of Treatment.	End of One Month's Treatment.
Weight 136 lbs.	Weight 139 lbs.
Temp. 98.3°.	Temp. normal.
Pulse 84.	Pulse 72.
Respiration ratio 40.	Respiration ratio normal.
Expectoration copious, thick, bloody.	Expectoration decreased and no hæmoptysis.
Night sweats none, sweats during day.	No sweats.
Appetite poor.	Appetite good.
Bacilli, Gaffky's scale No 1.	Bacilli Gaffky's scale No.—
Cavity left base front and back.	Improved condition of lung.

He tells me that he does not spit so much at the present time in one month as what he spat in a day before beginning the treatment; does not spit blood now. Appetite is very good, would not wish it to be better. Strength is much improved, and can work as well as ever he could; is a mechanic.

In an article dated May 14, 1887, which appeared in the *Journal of the American Medical Association*, a captious criticism is made, not upon the "Bergeon's Method of treating Phthisis," as it is headed, but dwelling mainly upon the American method of preparing the gases. Nothing is said as to the manner in which results good, bad or indifferent were obtained, but much ado is made as to the quantity of gases $C O_2$ and $H_2 S$ used. As I have given over 600 injections I believe that I am privileged to say with a certain amount of positiveness, that it is not of the slightest consequence as to the mode of preparation of the $C O_2$, enough should be given to carry sufficient $H_2 S$ into the economy to show the reaction within five to fifteen minutes from the time of administration. If the quantity is gauged in accordance with the capacity of the patient's bowels, no colic will ensue; when colic occurs it is due to mechanical distension of the bowels. The rules for the application of this system have been plainly laid down by Bergeon and Morel, and when faithfully followed, as described by them,[2] equal satisfactory results may confidently be anticipated, but not so when the apparatus, quality, etc., of gases have been garbled. In conclusion, let me say that this being but a preliminary series of observations, it might be going too far to agree with Bergeon, that this system alone is curative, but on the other hand, what the possibilities of its value are as an adjunct to the usual treatment of phthisis, may be seen from the beneficial results obtained, as shown in the above cases.

— The "celebrated" Dr. Schweninger has contracted to reduce the corpulence of the Czar. Terms, £1200 if successful, £500 and travelling expenses if not successful.

REPORT ON THE PROGRESS OF LARYNGOLOGY AND RHINOLOGY.

BY FRANKLIN H. HOOPER, M.D., BOSTON.

THE ILLNESS OF THE CROWN PRINCE OF GERMANY. THE PRESENT POSITION OF COMPLETE AND PARTIAL LARYNGECTOMY. RESULTS OF 327 CASES OF TRACHEOTOMY FOR CROUP. BLOODLETTING IN CROUP. MILK AND THROAT DISEASE IN CANTERBURY, ENGLAND. OCULAR TROUBLES OF NASAL ORIGIN. TIP-TILTED NOSES.

THE ILLNESS OF THE CROWN PRINCE OF GERMANY.

ACCORDING to a recent number of the *Medical News*:

"The Crown Prince began to suffer from catarrh and hoarseness last January, and was treated at that time by his physician-in-ordinary, Dr. Wegner, Director-General of Hospitals. A morbid growth on the left vocal cord was discovered by Prof. Gerhardt in the beginning of March, and he applied the electro-cautery, with but slight improvement resulting. On the occasion of the Emperor's birthday at the end of March, the Crown Prince was obliged to use his voice much. In the middle of April he was ordered to Ems, where he took the waters for a month, and then returned to Berlin no better. The growth was at this time found to have increased in size. Prof. von Bergman was called in consultation, and subsequently Prof. Tobold, of Berlin, and Dr. von Lauer, the Emperor's physician-in-ordinary and Chief of the Army Medical Department. They all agreed that the growth was cancer, but before doing an external operation they advised that Dr. Morell Mackenzie, of London, be summoned. Accordingly the Crown Prince telegraphed Queen Victoria requesting that Dr. Mackenzie be immediately dispatched to Berlin, and he arrived there on the afternoon of May 19th. He found that all necessary arrangements had been made to do an external operation.

"At 7.30 o'clock of the next morning Dr. Mackenzie, upon examination, found a small sessile growth of the size of a split bean, and he recommended that a portion of the tumor be removed by intralaryngeal operation for microscopic examination. Prof. Gerhardt and Prof. Tobold thought that this was impossible, but agreed that Dr. Mackenzie should attempt the operation the next morning. With the aid of forceps Dr. Mackenzie succeeded in removing a portion of the growth, which, after microscopic examination, Prof. Virchow reported consisted of inflammatory products. Dr. Mackenzie then left Berlin, but returned on June 7th, and performed a second intralaryngeal operation."

The following is the text of Prof. Virchow's report on the portions of the growth removed, as published in the *British Medical Journal* of June 18th.

"The two objects brought to me yesterday by General-Aerzt Dr. Wegner, displayed, when examined microscopically, the appearances of a coarse granular papillary outgrowths. Their rounded surfaces had a conglomerate, bluish-white, transparent, shining appearance, so far as they were in their natural state, but certain portions which had been exposed to the influence of catechu, exhibited a dull, brownish, somewhat crumbling appearance. The portions removed at the operation were somewhat retracted and hidden by the rolling inward of their edges. They consisted of a soft, fibrous tissue, from which shorter and longer shreds projected. The larger of the two pieces was 3 millimetres long and 2.5 millimetres thick; the smaller was about 2 millimetres broad and thick. But

these measurements probably do not accurately represent the natural dimensions, as the particles have diminished in size, owing to the retraction and to the folding of the sections after their extirpation.

"Microscopic investigations confirmed the diagnosis arrived at from the naked-eye examination:

"(1) The surface consisted everywhere of a very thick and dense membrane, with stratified epithelium cells. In many of the cells, gelatinous granules of large size were visible. Here and there lay a nest of cells lying in concentric layers. Toward the interior there was a similarly stratified layer of cylindrical cells (without cilia) implanted directly on the connective tissue.

"(2) The surface of the mucous membrane was covered with long papillary excrescences, which, besides the elements of the connective tissue, contained rather large vascular loops. Each nodule visible to the naked eye, on the surface, was formed by a papilla of this kind. As for the rest, the mucous membrane exhibited scarcely any modifications; larger granular and cell growths were only noticed in scanty quantities; the bloodvessels were only moderately dilated. Both portions removed included not only the mucous membrane, but extended through it into the submucous membrane. Hence, besides connective tissue with numerous fine elastic fibres, there was a large number of nerve bundles (with from four to six fibres) and their branches, and of small arteries and veins; at some points there were masses of the lobules of the mucous glands. Although it is proved by this that the incision reached parts situated deep below the mucous membrane, not a single spot that had undergone any appreciable change was discovered, despite the most careful examinations of these more deeply situated parts, especially on the extirpated side. All the essential changes affected the surface only. They prove that the tumor is an epithelial growth associated with papillary excrescences (wrongly described as papilloma) an affection termed 'pachyderma verrucosa.' At no point was the mucous membrane found to be invaded by the epithelial formations. The specimens now before me are of considerably greater scientific value than that laid before me on May 21st; in the particle then examined only scanty lesions of an irritative kind were seen; lesions only distantly to be compared with those found in the particles now examined; in all, probably, the irritative changes affected the periphery of the seat of the disease. It is evident that on the present occasion a more central spot was reached. Although this spot has become affected in a very marked manner, the healthy quality of the tissue on the extirpated portions, gives grounds for a very favorable prognosis. Whether such a prognosis be justifiable for the malady considered as a whole, cannot be concluded with certainty from the two pieces that were removed. However this may be, there is nothing in them calculated to awaken a suspicion of a further and more serious affection of those parts."

After the second operation, the Crown Prince proceeded to London to be under the care of Dr. Mackenzie. The progress of the case has been most favorable, and the growth, it is stated, has now been very nearly removed. Prof. Virchow has again made a thoroughly satisfactory report of portions sent to him to Berlin, for microscopic examination.

Laryngologists, perhaps, will best appreciate the difficulties of this important case, but all will recognize the masterly and scientific manner with which Dr. Mackenzie has conducted the treatment of his Imperial patient.

THE PRESENT POSITION OF COMPLETE AND PARTIAL LARYNGECTOMY.

During the past twenty years total extirpation of the larynx has been performed about one hundred times. In the majority of cases the operation was for carcinoma, secondly, for sarcoma, and thirdly, for stenosis due to other affections.

Dr. J. Solis Cohen, of Philadelphia, in 1883, in a paper entitled, "Does Excision of the Larynx tend to the Prolongation of Life?" expressed the opinion that excision of the larynx for carcinoma was unjustifiable, and that the greatest good to the greatest number, would be better secured by dependence on the palliative operation of tracheotomy. There is nothing in more recent statistics of this operation to induce any one to take exception to Dr. Cohen's estimate of this procedure. The immediate mortality of the operation is about forty-four per cent., and the disease recurs in forty-six per cent. of the recoveries. The mean duration of life of the living and well cases is less than seventeen months. The danger during the first few days is chiefly from septic broncho-pneumonia. According to Cohen it may be that the reduction of temperature to which the pneumogastric nerve is subjected, leads to pneumonia, and that the manipulations within the wound render it especially sensitive. When we reflect, he continues, that the majority of these operations of laryngectomy consume from one to three hours in their performance, we can fairly presume that the pneumogastric nerve is subjected to sufficient ordeal to excite an early pneumonia, quite independently of access of foreign matter to the lungs.

M. Léon Labbé, who described three cases of excision of the larynx at the last French Congress of Surgery, related that in one case, on the larynx being isolated, the patient turned pale and death-like, probably from contusion of the pneumogastric nerve. Artificial respiration was carried on for twenty-six minutes. The operation was then recommenced, and the patient recovered and lived for four months and a half.

Although the statistical results of excision of the larynx do not, as yet, warrant its performance, some important points have been learned about the technical details of the operation, and the after-treatment of the patient. By a careful selection of cases in the future, better results may be obtained. Mr. Butlin, of London, suggests that extirpation of the larynx for carcinoma, should be practised only for intrinsic carcinoma which is still limited to the interior of the larynx. He also says that if a surgeon is consulted by a patient suffering from laryngeal epithelioma, and there is nothing for it but excision of the larynx, he is bound to tell the patient (1) that it was a dangerous operation, with a mortality of from forty to forty-five per cent.; (2) that recurrence would probably soon take place; (3) that he would not even get much relief from distressing symptoms, for his difficulty in swallowing and breathing would be as great after as before the operation. It is evident that complete extirpation of the larynx for carcinoma should only be practised in very rare instances, if at all. In a patient, however, in good general health, where the disease is lim-

ited to a small portion of the interior of the organ, and with no involvement of the lymphatic glands, favorable results may be expected from partial extirpation.

Dr. Eugene Hahn, and other German surgeons advise this lesser operation for the reason that it is attended with a greatly reduced mortality, and followed by fewer recurrences and a larger number of permanent successes. The reported cases, however, are as yet few in number, and sufficient time has not yet elapsed to show that recurrence will not take place. But the results of three recent cases in England, so far as immediate recovery is concerned, are most encouraging. At a meeting of the Clinical Society of London, last November, Dr. F. Semon and Mr. Butlin reported two cases in which the operation of partial excision was undertaken for malignant disease, and both ended in rapid recovery. Five months had elapsed in one case since the operation, and three months in the other. The condition of both patients was then satisfactory.

Mr. Lennox Browne, in the *British Medical Journal*, February 5, 1887, reports an interesting and successful case. He states that he publishes the case at a period long prior to the time at which the real issue, that of immunity from recurrence, can be settled, because he believes that the difficulties of the operation, and also its immediate dangers, have been largely exaggerated.

He emphasizes the following points:

(1) Use of the raspatory for removing the tissues external to the cartilage, as the surest safeguard against hæmorrhage, as lessening the chance of septicæmia, and ensuring speedy recovery of the power of swallowing, etc. (2) The use of Hahn's tampon canula. (3) The use of perchloride of mercury in solution, and of corrosive sublimate gauze in preference to iodoform, as dressings for the wound. (4) The not too quick closing of the external wound, with the view of prolonging functional rest of the larynx without the irritation of a tracheotomy tube.

Mr. Browne concludes by saying: It is earnestly to be hoped that care will be taken in the selection of subjects for this operation, as otherwise discouragement will be given to its performance where other circumstances would be favorable. It is indicated in unilateral and intra-laryngeal epithelioma, and in recent non-infiltrating sarcoma. It is useless in pharyngo-laryngeal epithelioma, in which the larynx is invaded from the pharynx, and whenever there is implication of the cervical glands and structures adjoining the larynx. It is always possible, if on division of the thyroid cartilage the disease is seen to have extended beyond the limits suspected by prior examination, for the surgeon to desist from removal and to be content with having performed tracheotomy.

RESULTS IN 327 CASES OF TRACHEOTOMY FOR CROUP.

Dr. Robert W. Lovett and Dr. John C. Munro, formerly House-Surgeons at the Boston City Hospital, give, in a valuable article in *The American Journal of the Medical Sciences*, July, 1887, the results of the operation of tracheotomy performed for croup at that hospital, from the time of its foundation, in 1864, to January, 1887. Three hundred and twenty-seven cases are analyzed. Up to the year 1880, only 30 tracheotomies had been done, so that the greater part of the operations have been performed in the last six years. Our attention is called to the fact that a bad class of cases naturally come to a city hospital for operation, and in most instances, long after it has become advisable. The children are brought hurriedly for operation, often in a hopelessly bad condition. Of the 327 cases, 232 died, and 95 (29.05 per cent.) recovered.

Our space will only permit us to give the general results of this carefully-prepared report. The results of operation are above the average, in spite of the predominance of bad cases. They show that young children are especially liable to have extension of the diphtheritic process to the bronchi and lungs; in fact, that the chances are three to one that if they die, they will die of suffocation; that, in Boston, tracheotomy at the City Hospital is most fatal at those times when diphtheria is most fatal in the whole city, and incidentally, that the mortality per cent. from croup and diphtheria vary by the month in unison. That cases with membrane in the pharynx at the time of the operation are more likely to die than those where it is not present. That the mortality per cent. after tracheotomy rises steadily as the operation is done on the first, second, third, or fourth day of the difficult breathing. That nasal discharge, albuminuria, and enlargement of the cervical glands are symptoms of less moment than the character of the discharge from the trachea-tube, which is the most important index of the progress of a case, and that the recovery-rate varies nearly fifty per cent. between cases where the discharge is loose throughout, and those where it is gummy at any time.

The following table of all available reported cases of tracheotomy arranged by countries, is given for purposes of comparison:

	Total.	Recovered.	Died.	Per cent. Recovered
German authors,	5,795	1,851	3,944	31
German hospitals,	3,063	939	2,124	30
British authors,	433	138	295	31
French authors,	9,242	2,242	6,834	24
Various countries,	1,903	657	1,336	32
American authors,	1,327	308	1,019	23
	21,853	6,135	15,552	28

BLOOD-LETTING IN CROUP.

In a very interesting and suggestive paper "On the Remedial Value of Blood-letting,"[1] by J. A. MacDougall, M.D., F.R.C.S., Ed., we find the following few lines regarding its efficacy in croup:

"Before proceeding to allude to those conditions in which the benefit attending blood-letting is conspicuous and undoubted, I would make mention of the advantage which attends its employment in certain cases of simple croup. I am not likely now ever to forget, for the early writings on the folds of memory are the most indelible, the relief which I, when a little lad, suffering from croup, obtained by venesection. Emetics, hot fomentations, and the warm bath had all been employed, but with no benefit. The dreadful feeling of suffocation was still unrelieved, while following immediately the withdrawal of several ounces of blood from the arm, I was easy and comfortable. It would be a marvel, then, that if thus taught, it seemed the

[1] The American Journal of the Medical Sciences, July, 1887.

lesson of a *life* in its fullest sense, I should have denied the same relief to others, and thus it is that, in late childhood and early youth, when other means have failed, and when, in vigorous adolescents, cynanche laryngea is marked by the symptoms noted by Cullen: 'respiratio difficilis, inspiratio strephens, vox rauca, tussis clangosa,' then my trust and my expectation lie in a moderate phlebotomy."

MILK AND THROAT DISEASE IN CANTERBURY, ENGLAND.[2]

The medical officer of health of Canterbury has reported a sudden outbreak of throat disease, which, in eight days, attacked no less than 231 persons, without fatal effects in any instance. So far as can be judged, the epidemic was due to milk, for of 160 houses served from the dairy which is in suspicion, no less than 94 were affected, and, so far as can be gathered, out of 36 houses partly supplied from the same diary, and partly by other milkmen, 21 were affected. In the other instances of houses affected, the persons in question seem almost exclusively to have been those who were either attacked late during the outbreak, and under circumstances which admitted of their having derived the infection from antecedent cases, or else persons who may easily have partaken of the suspected milk elsewhere than in their own homes. So far, says the *Lancet*, the reports on the case are, we trust, incomplete, for by far the most interesting feature of the case is the implied sickness of animals in connection with the outbreak, and the history as to this is as yet very imperfect. Indeed, we only learn of a lamb in the suspected dairy premises having suffered from "sore throat," and of cows having had "diarrhœa." The connection now established between disease in the human subject and affections of a specific character in lower animals, and especially in cows, is of far too great importance to admit of such a case being passed over by such vague accounts in so far as these animals are concerned. It is to be hoped that skilled veterinary and pathological aid was secured, either through the Local Government Board or otherwise, and that a more complete report will be issued.

OCULAR TROUBLES OF NASAL ORIGIN.

Dr. Gruening, of New York, Dr. Boerne Bettman, of Chicago, and Dr. Gordon, of Springfield, Ill., have called attention to the importance of recognizing abnormal changes in the nose as the starting point of certain pathological conditions of the eyes and lids.

The connection between the nose and the eye is intimate, and the relations of the two are reciprocal. Thus, irritation of the nasal mucous membrane frequently produces lachrymation and other eye symptoms, and in the case of certain irritable eyes, exposure of the organ to a strong light brings on attacks of sneezing. Disease from one organ to the other may spread by direct continuity of tissue, and also through the medium of the circulatory and nervous systems.

The lachrymal passage is the connecting link between nose and eye. The mucous lining of the lids and eyeballs is but a continuation of that covering the inner surface of the nose and tear-ducts. This fact alone, Dr. Bettman thinks, ought to suggest the rationality of seeking in the nose the cause of epiphora, redness of the lids, and other abnormal conditions, provided the disturbances could not be traced to local causes. He then points out that it is only since the publication of Hack's monograph on the operative radical cure of migraine, asthma, hay fever, etc., that the nose has been regarded as the source of certain ocular complaints which have baffled the efforts of oculists. The nasal trouble will generally be found to consist of a swelling of the anterior end of the inferior turbinated body. The mucous membrane may show a perfectly normal appearance, indicating that the cause of the swelling is due to changes underneath it, in the cavernous spaces, which become filled with blood, bulging the mucous membrane outwards, until it at times reaches the septum. This swelling, and also swellings of other portions of the nasal cavities, can give rise to reflex neuroses in various organs, which can, furthermore, be allayed by destroying the seat of irritation by operative measures. Thus Hack accounts for certain forms of migraine, asthma, hay fever, supra-orbital neuralgia, vaso-motor reflexes of the skin of the face, epiphora, redness of the lids, turgescence of the conjunctival bloodvessels, and photophobia.

Dr. Bettman cites cases that did not yield to the ordinary treatment directed to the eyes, but improved immediately after eradicating the abnormal conditions in the nose.

Dr. Gruening states that in simple cases, the instillation of cocaine into the nostrils often affords a satisfactory test as to whether the ocular trouble is dependent on nasal irritation or not, for if it affords relief to the eye symptoms, we may conclude that the latter are to be attributed to the condition present in the nose. He relates several cases of his own, as examples in which the eyes were affected for many years, in consequence of comparatively mild affections of the nasal mucous membrane, and in spite of the most persevering and skilful treatment directed to the ocular condition, but in which the eye trouble promptly disappeared as soon as the nasal affection was removed by appropriate treatment.

All the cases, however, were not of this simple class, and he speaks of several in which the reflex eye symptoms were due to more serious pathological conditions of the nasal cavities. In them, also, the eye trouble disappeared as soon as the source of irritation in the nose was removed. In one instance, where the patient had suffered for many years, the eyes were permanently cured on the very day that a large mass of hypertrophied tissue was removed from the nose. During the past two years, he says, he has met with some two hundred cases in which he could refer the ocular symptoms to nasal trouble; but the treatment, which varied according to the circumstances of the case, was not always successful. In most of the unsuccessful cases, however, the patients had disappeared before the treatment was completed, or, perhaps, was fairly commenced. Still, in about one hundred and fifty of the two hundred cases, complete relief had been afforded by the removal of abnormal conditions of the nasal passages.

Among the symptoms mentioned as most frequent in these cases of reflex eye trouble, are: Burning and smarting sensations in the eyes, more pronounced in the morning; inability to fix an object in ordinary daylight; irritation and gluing together of the lids; extreme sensitiveness to cold and wind; lachrymation. Other characteristics were: inefficiency of ocular treatment, and efficiency of nasal treatment, even in spite of the absence of nasal symptoms.

[2] Medical News, October 9, 1886.

Dr. Gordon describes a form of conjunctivitis dependent upon disease of the intra-nasal tissues. This conjunctival disease, he says, is chronic inflammation of the conjunctiva and the connecting tissues, accompanied by increased thickness of the membrane, especially of the palpebral portion, which is very slightly roughened, giving it somewhat the appearance of trachoma in a mild form. The tarsal cartilages, tarsal glands, and ciliary follicles are more or less involved, with marked lachrymation and photophobia; pain is sometimes intermittent, more severe in the afternoon. The disease in the nose is usually a chronic rhinitis, of the hypertrophic character; mucous membrane exquisitely sensitive, with an abundant flow of thin, watery mucus.

A marked and important character of the conjunctivitis is its chronicity; it is not limited by weeks or months, but years. It yields slowly and only temporarily to the orthodox method of treatment of chronic conjunctivitis.

Dr. Gordon believes that the successful management of this form of conjunctivitis depends upon the proper treatment directed to the nasal passages.

TIP-TILTED NOSES.[2]

The influence of the shape of a man's nose in determining the good or evil fortune of his life has not escaped the attention of physiognomists. That eminent social philosopher, Mr. Shandy, whose lucubrations have attained so wide a currency, thanks to the filial admiration of his son, Tristram, truly observed that "no family, however high, could stand against a succession of short noses"; by "short noses," probably to be understood that form in which the organ is not only curtailed in length, but so distorted in form that it is "tip-tilted, like the petal of a rose." This poetical simile but imperfectly expresses the true state of the matter. For a short time, while the *beauté du diable* lasts, the tip-tilted nose may be forgiven in a woman, but for the greater part of existence it is a continual social agony to its unfortunate possessor. Such sufferers will rejoice to hear that their sad case is not beyond the reach of plastic surgery. Dr. John O. Roe, of Rochester, N. Y., has devised an operation for "the correction of the deformity," which is easily performed. He most philosophically remarks that "the nose does not appear ugly by reason of the fact that its size is disproportionate to that of the face (for noses vary greatly in this respect), but by reason of the disproportionate relations to one another of the different parts of the nose itself." Accordingly, having deadened the sensibility of the interior of the nose with cocaine, he pulls up the end of the nose, reflects the mucous membrane, cuts away the superfluous tissue which causes the organ to be tip-tilted, and then, if necessary, moulds a splint — a saddle, as it were — to the top of the nose, so as to make it, while healing, assume the desired aquiline shape. In other cases, where the large end is due to the cartilages of the nose being bulged outwards too much, he cuts them through with a thin-bladed knife, and then applies his splint or saddle. In neither case is the operation at all serious. There is no scar, for the skin is not cut through, and the results, if we may judge by the drawings made from photography taken before and after, leave nothing to be desired.

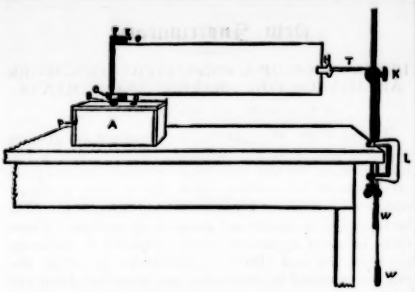
New Instruments.

DESCRIPTION OF A SIMPLIFIED CLOCK-WORK APPARATUS FOR GRAPHIC EXPERIMENTS.

BY F. W. ELLIS, M.D., SPRINGFIELD, MASS.

THREE kinds of apparatus are required in graphic experiments: first, a contrivance for imparting a uniform motion to the recording surface; secondly, an arrangement for writing upon the moving surface; and thirdly, a driver for transmitting the movement to be recorded to the second form of apparatus. These three forms of apparatus are all required in ordinary physiological and clinical experiments in which the graphic method is employed, and together form the complete recording apparatus.



We have no good name for the first class of instruments — perhaps graphic-motor would be as good as any. The word kymograph, or kymographion, is sometimes employed to designate this species of apparatus, but, as the word is also used to denote instruments belonging to the second class, as the original kymograph of Ludwig, Fick's spring kymograph, etc., it only tends to confusion to employ it in this connection.

In the ordinary forms of graphic motors some kind of clock-work is usually employed. In large laboratories, gas-engines, electric, hot-air, and water motors have been used to impart the required motion to the apparatus, but, ordinarily, clock-work driven by a weight or spring is resorted to for this purpose. Experience has taught the writer that even large laboratories are apt to be inadequately supplied with instruments of this kind. The cost of the instruments constructed after the models of Ludwig and Marey is so great that well-equipped laboratories cannot afford more than one or two of them. Several experimenters, working together, are liable to be embarrassed for want of a sufficient number of recording instruments. To many clinical investigators these instruments are inaccessible. There are also enthusiasts, carrying on experimental researches in private, who are indisposed to make the large outlay required to procure the complicated Ludwig or Marey apparatus. There are, moreover, certain requirements for particular purposes which the instruments mentioned do not possess; these are portability, compactness, and easy adaptability to special conditions.

Reichert[1] described two ingenious arrangements of simple construction to take the place of the complicated graphic motors. The apparatus was, however, bulky and could not be conveniently transported. The apparatus to be described is exceedingly simple, is easy to construct, costs very little, and is quite efficient. It is amply sufficient for most graphic purposes, and is particularly well adapted for clinical work. It can be easily modified for special purposes, and very long tracing can be taken with it when required.

The figure gives an outline sketch of the apparatus. The clock-work is enclosed in a small covered box A. The axle for the minute-hand projects through a small hole in the cover, and is represented at B. A wooden spool C, about 12 centimetres long, and having a hole in the centre of its lower end, is fitted to the axle, and is retained in a perpendicular position by means of the

[1] Two new Kymographions and a Time-Recorder, Philadelphia Medical Times, Vol. XII, p. 267.

wooden upright D having a projection E at right angles to it. A pin F in the centre of the upper end of the spool is held in a notch in the piece E by a pin G. A clamp L, to which is fastened a brass rod, can be fastened to one end of a table. A short piece of brass K has a hole in its centre through which the rod passes and upon which it can be clamped at any height by means of a binding-screw. Two small pulleys are affixed to the ends of this piece. Two strings pass over these pulleys. One end of each string is fastened to a garter-clamp H, and the other to a small weight W. The clamps are fastened to each end of the paper for the tracing. One end of the paper is passed around the wooden roller, and the strings are placed upon the pulleys. The paper is then retained in its position by the traction of the weights. The clock-work is an ordinary eight-day movement. The pendulum and escapement are removed. A piece of sheet brass is fastened to the axle of the scape-wheel to serve as a regulator. A steel spring, one end of which, P, projects through the front of the box, is fastened inside the case in such a way that it serves as a lever which can be pressed against one of the wheels and so stop the apparatus. By employing spools of different diameters the rate of movement of the paper can be varied as desired. When a very slow rate is required, as is necessary in some protracted experiments, extending over hours, or even days, a marine clock-work can be substituted for the ordinary pendulum movement.

It is evident that tracings of great length can be taken with this apparatus. By turning the box upon its back, horizontal tracing can be obtained.

A very efficient method for smoking the strips of paper is the following: A circular piece of wood, an inch or more in thickness, is sawn from a board. A short brass or iron rod is driven through the centre of the wooden disc. The paper is made to envelop the disc and is fastened with a tack. By revolving the wheel over the naked flame of an oil lamp the paper can be very evenly covered with a coating of carbon.

Ordinarily very light weights are sufficient to keep the paper smooth. When larger weights are used, it will be necessary to fasten the box to the table by means of a clamp or some other simple device.

— Professor Braune, of Leipzig, after a thorough investigation of the mechanism of the hand, is said to have constructed a new sword-handle on anatomical principles, which exactly fits the hand, and can be held with absolute security.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

MARCH 16, 1887. DR. JAMES R. CHADWICK, in the chair.

DR. JOHN HOMANS, 2d, read a paper entitled

SUPPLEMENTARY OVARIES.[1]

DR. CHADWICK. While I do not regard the question settled as to the dependence of menstruation upon functional activity of the ovaries, the preponderance of evidence seems to me to be adverse to that theory. In his paper "Sur la menstruation après l'ovariotomie et l'hystérectomie," Paris, 1880, Ormières published brief extracts of forty-five cases of double ovariotomy in which the patients subsequently menstruated with reasonable regularity, and forty-eight cases in which, after the same operation, they failed to menstruate persistently. Dr. Reeves Jackson,[2] in his article on the "Ovulation theory of Menstruation" reproduces a table by Dr. John Goodman, of double ovariotomies, containing twenty-seven cases in which fourteen patients menstruated subsequently with more or less regularity. From these two tables it is apparent that menstruation persists after the removal of both ovaries in about half the cases. Until these figures shall have been controverted, we cannot accept the theory that menstruation is dependent upon the presence of the ovaries or adduce the occasional existence (in four per cent. of the cases), of supplementary ovaries in explanation of the persistence of menstruation when two ovaries have been removed. Furthermore, if, as stated in the paper to which we have listened, the supplementary ovary is generally nourished from one of the ordinary ovaries, how can it be supposed to be nourished and continue to functionate after the removal of the other two ovaries.

DR. FITZ said, I do not remember to have ever found what was unquestionably a supplementary ovary, and I had the impression that the number of well authenticated cases was very small, perhaps three, and less than a half a dozen. As the existence of supplementary ovaries has been conspicuously brought to the attention only within a few years, many cases may have been overlooked. It is, therefore, not unlikely that this condition will be found in the future to a greater extent than in the past.

DR. J. W. FARLOW read a paper entitled

THE VALUE OF THE BLUE DISCOLORATION OF THE VAGINA AS A DIAGNOSTIC SIGN OF PREGNANCY.[3]

DR. HOMANS asked Dr. Farlow why he used the word "blue" if the color is of a wine-red or claret color.

DR. FARLOW replied that the usual way of referring to the color is to call it blue. It is blue at first, and later assumes a marked violet or port-wine color.

DR. VICKERY asked if the color was found in extra-uterine pregnancy.

DR. FARLOW said he had seen but few such cases, and in those the color was not noted. In conclusion, he spoke of a blue color which is not infrequent about the posterior commissure of the vagina, but which seems

[1] See page 50 of the Journal.
[2] American Journal of Obstetrics, Vol. 9, p. 550, 1876.
[3] See page 49 of the Journal.

to be connected with the vessels of the rectum and not with those of the uterus.

DR. CHADWICK. As I have been taking notes on the "Value of the Bluish Coloration of the Vaginal Entrance as a Sign of Pregnancy," for ten years, and read a paper on the subject at the last meeting of the American Gynæcological Society, I venture to give my conclusions. The number of cases in which my data were complete included 281 pregnant and 56 non-pregnant women.

Of the 281 pregnant women, the color was practically absent —

At the end of	2	months in	51	per cent.	of the cases.
"	2½	"	31	"	"
"	3	"	17	"	"
"	3½	"	8	"	"
"	4	"	8	"	"
"	4½	"	9	"	"
"	5	"	4	"	"

The color was *suggestive* of pregnancy —

At the end of	2	months in	34	per cent.	of the cases.
"	2½	"	41	"	"
"	3	"	27	"	"
"	3½	"	45	"	"
"	4	"	30	"	"
"	4½	"	4	"	"
"	5	"	20	"	"
"	5½	"	30	"	"

The color was *diagnostic* —

At the end of	2	months in	13	per cent.	of the cases.
"	2½	"	28	"	"
"	3	"	46	"	"
"	3½	"	36	"	"
"	4	"	63	"	"
"	4½	"	86	"	"
"	5	"	72	"	"
"	5½	"	70	"	"

After (and including) the end of the sixth month, the color was *diagnostic* in all but one case, in which it was *suggestive*, and one in which it was *doubtful*.

The analyses on the positive side are supplemented, and the general conclusions strengthened, by the evidence of the following table, compiled from the records of patients who, for more or less good reasons supposed themselves to be pregnant.

TABLE OF 56 WOMEN WHO PROVED NOT TO BE PREGNANT.

Period after menstruation.	Valueless.		Suggestive color	Diagnostic.		Total
	No color	Doubtful color		Characteristic color	General deep color	
1 week	1	..	1	..	..	2
2 weeks	2	..	..	..	..	2
3 "	2	..	..	..	..	2
4 "	5	3	..	..	1	9
5 "	3	2	1	..	..	6
6 "	12	1	..	..	..	13
7 "	1	..	..	..	..	1
2 months	6	..	..	..	..	6
2½ "	2	1	..	..	..	3
3 "	4	..	..	..	..	4
4 "	1	2	..	..	..	3
5 "	3	..	1	..	..	4
6 "	1	..	..	..	..	1
Total	43	9	3	..	1	56

My conclusions with regard to the blue color were:

"(1) That its absence is not to be accepted as evidence that pregnancy does not exist, especially in the first three months, where satisfactory evidence is most needed."

(2) *That from (and including) the second month, this color is generally present, and often of such character as to be diagnostic.*

I have found the color of great assistance in making a diagnosis in the early months of uncomplicated pregnancy, and in the later months in cases of *retroversion of the pregnant uterus; extra-uterine pregnancy; in pregnancy complicated with fibroid tumors of the uterus or with ovarian tumors; in pregnancy occurring in women with very fat or tense abdominal walls; when the existence of pregnancy was unknown or concealed; when menstruation persisted after conception;* and *when conception has occurred during lactation without the intervention of menstruation.*

MASSACHUSETTS MEDICO-LEGAL SOCIETY.

W. H. TAYLOR, M.D., RECORDING SECRETARY.

JUNE 7, 1887, the tenth annual meeting was called to order in the rooms of the Boston Medical Library Association, at 11.20 A.M., by PRESIDENT WINSOR. Twenty members were present. Records of the last meeting were read and approved.

MEDICAL EXAMINER HOLT of the committee to prepare a blank form to be used in reporting autopsies made his report, recommending a printed form which he presented, and also advising the purchase by each medical examiner of Virchow's Post-mortem Examinations.

The report was accepted, and MEDICAL EXAMINER HOLMES moved adoption of the printed form. Considerable discussion ensued, and it was finally voted to reconsider the vote accepting the report of the committee, and to refer the blank form to it again with request to report at the next meeting of the society.

Voted, on motion of MEDICAL EXAMINER WRIGHT that a copy of the blank form be sent to each member with the request that he examine it and suggest to the committee any changes that seem desirable.

The following officers were elected for the ensuing year: President, F. Winsor, M.D.; Vice-president, J. G. Pinkham, M.D.; Treasurer, C. C. Tower, M.D.; Corresponding Secretary, B. H. Hartwell, M.D.; Recording Secretary, W. H. Taylor, M.D.; Standing Committee, F. W. Draper, M.D., S. D. Presbrey, M.D., A. F. Holt, M.D.

PRESIDENT WINSOR announced the death of G. P. Pratt, M.D., of Cohasset, a member of this society.

MEDICAL EXAMINER TOWER briefly referred to the life and character of Dr. Pratt.

On recommendation of the Executive Board the following gentlemen were elected to active membership: Medical Examiners, Drs. J. W. Spooner, of Hingham, J. Alban Kite, of Nantucket, T. M. Durell, of Somerville, Wm. Holbrook, of Palmer, W. F. Stevens, of Stoneham, G. M. Morse, of Clinton, J. G. Hayes, of Ipswich.

Charles Harrington, M.D., of Boston; and Hosea Kingman, Esq., District Attorney for the southeastern district were elected associate members.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, May 16, 1887.

DR. IRA B. READ read a paper on

TUBERCULOSIS OF THE JOINTS.

Although this was a strumous disease, and attended with the strumous diathesis, he said, it did not necessarily follow that the sufferer must have always been

a victim of such a diathesis, any more than it followed that he who died of pulmonary phthisis must have inherited it. Nor, on the other hand, did it necessarily follow that some injury must have been sustained. Dr. Read held, therefore, that each of these causes might claim its victims, but that to neither belonged the sole claim. Either, he believed, might act without the other, or both might act in conjunction. As regards prognosis, he thought that if the trouble was recognized early, the patient could be given reasonable assurance of a cure; but if this occurred at the second or third stage of the disease recovery would take place if at all, only after a long and tedious confinement.

The treatment was both constitutional and local. In the first stage we had an ordinary inflammation to treat, locally, but instead of depleting the patient, as might otherwise be done, it would be necessary to nourish and sustain him with nutritious food and tonic remedies. One thing must be peremptorily insisted on, namely, complete rest. There is already an overtaxed system, and nature must have an opportunity for recuperation. The indications were to soothe pain, quiet spasmodic action, give rest to the part, and build up the constitution. Should there be a detached fragment of necrosed bone, it should be removed. The sinuses should be kept as free as possible, and frequent injections of antiseptic solutions were required. Anchylosis must be guarded against, as in any other condition threatening it. Whatever would give rest and comfort to the affected part, bandages, splints, extension, should be employed; but it was to be constantly borne in mind that behind the swollen, or open and discharging joint, there was the patient, emaciated, weak, weary and nervous, who was to be unceasingly watched and sustained.

While the disease was peculiar to childhood, as a rule, there were exceptions, and Dr. Read then went on to describe a case which had been under his charge for several months, in which the patient was sixty-two years of age. He had always enjoyed good health up to the autumn of 1882, when the left shoulder-joint became affected. There was afterwards prolonged suppuration, with open abscesses, which subsequently healed, and in the winter of 1884 both ankles became affected, though without suppuration, and his general health was much impaired. In the winter of 1885, abscesses formed in both and there was a discharge of pus and blood. In the summer of 1885, an abscess formed on the great toe which discharged for some weeks. The right ankle healed in about six months, with the exception of two small openings, through which there is up to the present time occasionally a discharge of thin purulent fluid. The left ankle is still open and discharging pus, although not very freely. In the autumn of 1886, the knee began to swell and become painful, so that he could not walk. Up to this time he had been able to attend to his business daily, with but few interruptions.

In February last, Dr. Read was asked to take charge of the case, and he described in detail the conditions existing at that time. Up to this date the patient had been sitting up every day, but Dr. Read insisted on his going to bed and remaining there. Absolute rest was secured for the affected joints, gentle pressure was made by means of a woollen roller, and the opening in the ankle dressed with iodoform and a covering of oakum. Stimulants and the most nutritious diet was resorted to, but the patient was unable to take cod liver oil. Under this treatment there has been very marked improvement in the constitutional condition and the local symptoms.

DR. LAURENCE J. MCNAMARA read a paper on

RESPIRATORY THERAPEUTICS IN THE TREATMENT OF PHTHISIS PULMONALIS.

He would limit his remarks, he said, to one division of the subject, namely, the local treatment of phthisis by medicinal agents applied to the interior of the respiratory tract in finely divided particles. He did not propose to discuss the constitutional remedies supposed to act locally by elimination, or the treatment of pulmonic disease by the use of means to increase or diminish the air pressure, either in the air respired, or on the body surface.

The contention of different theorists, he went on to say, as to whether pulmonic phthisis was of a primary tuberculous nature, or whether the tuberculous element was of secondary importance, had kept alive the spirit of scientific research, even though the death-rate did not visibly diminish. To the followers of Laennec, however, the praise of success was due. The fierce antagonism that met his statement of the primary nature of the tuberculous element was the beginning of many experiments by late observers; and it was the sincere belief of the author that to his final insistance on the tuberculous nature of this disease the discovery of its specific nature was to be ascribed. The brilliant discovery of Koch in successfully isolating by his peculiar method of staining the bacillus tuberculosis seemed to him but the logical conclusion of such reasoning.

The importance of the bacillus and the infectious nature of the disease admitted, the necessity of using means to retard the further development of the organism, or of destroying it, and the placing of the exposed person in an atmosphere devoid of its presence, at once became apparent. The acceptance of this idea of infection by the profession in general, would be the dawning of a new day in the treatment of consumption. The possibilities of relief and cure became bright with the expectation of success, and the idea of prophylaxis assumed prominence. The changing of an infectious pulmonary discharge to one devoid of dangerous elements was the logical sequence of putting the theory into practice. He did not, however, wish it to be understood that he considered the antiseptic treatment of phthisis the only form of treatment worthy of application to the diseased lung. He believed that it was at present a necessary and most important means of modifying the course of the disease; but the physical conditions caused by the extension of the inflammatory irritant would call, of course, for other methods of treatment.

The number of mechanical appliances devised and in use, to reduce fluid of a medicinal nature to the finest spray, during the last few years, had been very great; but the majority of these were, unfortunately, of no use. That we could, however, produce a spray of sufficient fineness to pass the larynx and penetrate beyond the larger bronchi could not be denied. The use of compressed air and the employment of tubes with very minute openings had been of late years generally used by those interested in this branch of therapeutics. About four years ago Dr. McNamara said his attention was attracted to an in-

halation apparatus consisting of a funnel-shaped glass globe with two openings; one for the attachment of the metallic disc holding in its centre the spray-tubes, and the other, immediately opposite, terminating in a long mouth-piece. The fluid to be atomized was placed in the globe, and a tube of rubber connected the fluid with one of the spray-tips; while the other tip had a connection with a cylinder of compressed air. The globe rested on a bracket capable of being raised or lowered as required. The patient, standing with head elevated, placed the mouth-piece in his mouth and inspired; allowing the expired air to escape through the nostrils.

His first impression was that this apparatus was of similar nature to many others tried before and found wanting, but experience in its use had convinced him of its practical utility. The spray produced in the globe consisted of a central stream of very great attenuation, the larger particles of the atomized fluid being projected against the sloping sides of the globe, beyond the opening. These larger particles becoming condensed, fell as drops into the original solution, and did not escape through the opening. The mist that passed through the mouth-piece had no such momentum as to cause its entire condensation, and would not wet the hand when held before it. Ordinary inspiratory efforts would carry the spray into the lower respiratory passages. The compressed air he obtained from a large cylinder, allowing it to escape into a smaller one before reaching the spray-tubes, and, by this method, keeping the valves partly opened, he obtained constant, steady pressure in the smaller cylinder, and consequently, the same character of spray. The pressure used varied from fifteen to twenty pounds, and never exceeded this limit. He has been using this apparatus for nearly eighteen months.

When he began this form of treatment, it was with the idea that he could relieve, in many instances, many of the distressing symptoms in his phthisical patients; but, noticing the marked amelioration of the condition in the majority of instances, he determined, some months ago, to keep more exact records of temperature, pulse, respiration, and expectoration, noting especially the presence or absence of the bacilli, and the effect of the treatment upon them. The whole number of cases treated was between fifty and sixty, but as nearly one-half used the treatment but a few times, and at irregular periods, they were excluded from the account. The cases worthy of mention embraced almost all the forms of phthisis, except the stage of excavation, and the patients remained under treatment from one week to nearly eight.

Under this method of treatment, the cough and expectoration diminished, and in those treated the longest, the cough quite disappeared. The bacillus was found in every one of these cases, and was always present, even to the termination of the treatment, with the exception of one instance, although the number of bacilli was visibly diminished. When the treatment was discontinued, however, the symptoms had in most cases disappeared. One illustrative case Dr. McNamara described in detail. Having described the physical signs, and stated that the temperature varied between 98.8° and 101°, he said that the sputum contained bacilli. He placed the patient, who was a female, twenty-three years of age, on iron, quinine, and strychnine, and gave her daily inhalations of the following solution:

℞ Sodii bicarb:
Sodii biborat: aa ʒj.
Acid. carbolic: gtt. xx.
Glycerinæ: fʒij.
Listerine: fʒij.
Aquæ destillat: fʒxvj.
M.

When this treatment had been continued for nearly two weeks, the expectoration was found to have increased, but its purulent character had changed to one more mucoid. The small, white specks, used to determine the presence of the bacillus, became less numerous in the sputum, though still present. The severity of the cough was lessened, and the general health had begun to improve. He then placed her upon an inhalation of the dark extract of pinus canadensis, Lugol's solution (one to five drops to the drachm), carbolic acid, and distilled water. She remained under treatment regularly for almost three weeks longer, and then refused to continue the daily treatment, although consenting to come to the office two or three times a week.

When she abandoned the daily inhalations, he examined the slight discharge raised during the day (about three ounces), and, notwithstanding repeated examinations, he failed to find any evidence of the presence of the tubercle bacilli. About three months afterwards, he again examined the sputum for bacilli, and found none. The other cases were subjected to the same rigid tests, and bacilli were found in every one of them, even when the distressing symptoms had disappeared.

Dr. McNamara said, in conclusion, that there was no claim on his part to any originality in the method of treatment described. He again called attention to the fact that, although the cases were relieved of their symptoms, and the evidence in many instances pointed to a cure of the process, the scanty expectoration still contained bacilli, except in the case of the young woman referred to. In her case the vesicular murmur returned, and the râles disappeared, and, in addition, the bacillus also disappeared. On account of the difficulties attending the systematic use of such a method of treatment in private practice, he thought that it should be carried out in some special institute, where it could be combined with the pneumatic method, when the physical condition of the patient called for the employment of the latter.

Dr. E. G. Janeway said that it was difficult, in the first place, to carry out any plan of antiseptic treatment that would fully reach the affected parts, and difficult, in the second place, to appreciate the amount of disease present in many instances. By inhalation methods, we might be able to benefit a certain proportion of cases, but the conditions present were often such that the application would be carried to the sound tissues of the lung, rather than to the affected parts. It was well known how much difficulty there was in favorably affecting a case of tuberculosis when the parts involved could be readily reached, as, for instance, in tuberculous ulcers of the mouth, gums, tongue, or leg, and the difficulty must necessarily be much greater when the diseased part was as inaccessible as the lung. He thought inhalations might act favorably, however, in arresting the process by affecting the neighboring sound tissue. Again, it was a fact that in cases of chronic phthisis, attacks of capillary bronchitis and broncho-pneumonia sometimes occur, making them appear like acute tuberculosis, and, under these circumstances, the violent symptoms

usually subsided in a short time. There were, therefore, many cases in which one might be led to suppose that the tuberculous process was much more advanced in the lungs than was usually the case, and he believed that some of the cases reported as being so much benefited by the Bergeon treatment were of this character.

DR. H. M. BIGGS said that such applications as those referred to in the paper no doubt had a soothing effect upon the mucous membrane. They had no effect upon the bacilli, however, even when applied directly to them, and if we did use solutions which were strong enough to destroy them, we would produce an amount of irritation which could not be borne by the patient. Inhalations in the form of spray were unquestionably useful in aiding expectoration and the resolving of the products of inflammation, as well as for their disinfectant action in the upper air-passages; but, as a rule, he thought our main reliance in the treatment of phthisis at the present time must be placed on constitutional measures, including the selection of a suitable climate, wherever this was practicable.

In closing the discussion, DR. MCNAMARA said that he had not claimed that the inhalations would kill these germs. As a matter of experience, however, he had found that many of his patients improved so greatly under their use that all symptoms disappeared, although, as he had stated in the paper, the bacilli, with the exception of but a single case, persisted after the symptoms were gone.

PENNSYLVANIA STATE MEDICAL SOCIETY.

A VERY interesting meeting, the thirty-eighth annual session, of the Medical Society of the State of Pennsylvania has just been held at Bedford Springs, a health resort whose reputation was great in former days, and whose healing waters still preserve their virtue. Dr. S. H. Gump, of Bedford, was the Chairman of the Committee of Arrangements, and delivered an eloquent address of welcome on the morning of the first day, June 29th. The Committee on the organization of a State Board of Medical Examiners, reported that the bill which had been so carefully framed by the Committee to establish such a board, had failed to pass the Legislature. A resolution was submitted, requesting each County Society to consider the subject of a State Examining Board and to appoint a special committee to co-operate with the committee of the State Society. The resolution was adopted.

"The Address in Surgery" was read by Dr. J. S. Murdoch, of Pittsburgh, who considered the recent advances in surgery, especially connected with the adoption of the antiseptic method of dressing wounds. He devoted considerable time to discussing the advantages of the Chopart amputation, and exhibited casts showing admirable results. The "Address in Ophthalmology" was delivered by Dr. Charles S. Turnbull, of Philadelphia. "A Report on Hydrophobia in 1886" was read by Dr. Charles W. Dulles, in which the uncertainty of the pathology was insisted upon, as well as the unsatisfactory character of the testimony which had been urged in favor of the so-called Pasteur treatment.

Dr. John V. Shoemaker described a method of treatment of diseases of the skin by medicated plasters, a number of useful combinations were exhibited. A banquet given by the Bedford County Medical Society very pleasantly terminated the first day's proceedings.

On the second day, the first scientific paper read was the "Address in Medicine," by Dr. Frank Woodbury, of Philadelphia. He claimed that more exact conceptions of disease, based upon observation, both *intra-vitam*, and *post-mortem*, distinguish the medicine of to-day, and necessarily are working a revolution in therapeutics. Sutton's investigations into the genesis of the bacillus tuberculosis, apparently prove that it has been evolved from some harmless form by passing repeatedly through the intestinal canal of grain-eating fowls, thus acquiring the habit of growth at an elevated temperature. The probability of the bacilli, of cholera, dysentery, or typhoid fever, having their origin in this, or a similar manner, was referred to. Since some bacilli excrete poisonous chemical compounds (ptomaines), it was believed that immunity from future attacks is purchased by a sort of acclimatization, the system becoming accustomed to them just as it sometimes does in the case of morphine, alcohol, or tobacco. It was suggested that immunity from contagious disease might be attained by chemical agents, that is, quinine or arsenic prevents malarial infection; sulphuric acid or alcohol protects from cholera, etc. This is preferable to inoculation because more under control. Vital resistance can also be increased by gymnastics, and by massage. The employment of the blind in the practice of massage, as in Japan, was urged for adoption in this country, in order to popularize this useful method. Since artificial alimentation of infants is a great source of enfeebled vitality, the use of electricity as a stimulant to the mammary gland after parturition, was recommended. Even the breasts of virgins might be made to functionate and be utilized in this way, as suggested by Pierron. Thus an unlimited supply of wet-nurses could be obtained, with a reduction in the demand for baby-foods, and a corresponding falling off in infant mortality.

Dr. Traill Greene, of Easton, read a brief communication on "Palatable Therapeutics," in which he contrasted modern medical practice with that of the days of crude drugs. He claimed that it is unnecessary to administer a medicine in a form that will be unacceptable to the most fastidious palate, and denounced the practice of giving nauseating or unpleasant remedies.

Dr. George Stubbs, of Philadelphia, read a communication favoring the use of "Iodoform in Surgery," and Dr. Wm. F. Waugh condemned "the New Methods of the Treatment of Phthisis," by rectal enemata of gas, and defended the old methods. In the afternoon, Dr. S. Wolfe, of Skippack, Pa., read the "Address in Obstetrics," principally discussing the use of antiseptics during and after labor. Dr. John H. Packard read the "Report of a Case of Right Inguinal Colotomy," for strictures of the rectum and descending colon, with very satisfactory results. Dr. Wm. C. Bane reported two cases of Nystagmus, one with myopic astigmatism, the other hypermetrophic astigmatism. Both were relieved at once by appropriate glasses. Dr. S. S. Cohen considered modern methods in the Treatment of Pulmonary Consumption." The Salient Points in the treatment of Pulmonary Consumption" was read by Dr. J. T. Mays, of Philadelphia, and Dr. Edward Jackson followed with a paper on "When and How to Use Mydriatics in the Eye."

A number of interesting topics were suggested in the papers that were read only by title.

Dr. R. Davis, of Wilkes-Barre, President of the Society, read a very interesting annual address defending the profession from the charge of therapeutic nihilism, and reciting some triumphs of modern medicine.

The third day was opened with the "Address in Hygiene," by Dr. J. D. Thomas, of Pittsburgh, which elicited considerable discussion on sewerage, and the best means of utilizing or destroying human excrement and sewage.

At the business session the sum of $1,000 was appropriated for a contribution to the International Medical Congress, and about $200 was added by individual subscriptions. Five hundred dollars was appropriated towards the erection of a monument to Dr. Rush at Washington, D. C. R. J. Levis, M.D., of Philadelphia, was elected President for the ensuing year, O. N. Allis, M.D., Treasurer; Wm. B. Atkinson, M.D., Secretary; John H. Packard, M.D., Chairman of Committee of Arrangements. Dr. E. R. Sayer was appointed to deliver the Address in Medicine; J. S. McCann, M.D., the Address in Surgery; Theophilus Parvin, M.D., Obstetrics; H. C. Wood, M.D., Nervous Diseases; J. Randall, M.D., Ophthalmology. The next place of meeting will be Philadelphia, time the second Tuesday in June, 1888, the Society to continue in session for four days.

Recent Literature.

Transactions of the Eighth Annual Meeting of the American Laryngological Association. New York: D. APPLETON & Co. 1887.

This volume contains the papers read at the annual meeting of this active and flourishing association, held in Philadelphia, in May, 1886. There are twenty-five papers in all, of scientific or practical value, and they cover nearly the whole domain of the upper-air tract. The volume is well printed and neatly bound. It reflects credit upon the publishers, and upon the literary skill of the Secretary of the Association.

A Treatise on Diphtheria Historically and Practically considered, including Croup, Tracheotomy and Intubation. By A. SANNÉ, Docteur en Médecine, etc., Paris. Translated, Annotated, and the Surgical Anatomy added. Illustrated. By Henry Z. Gill, A.M., M.D., LL.D., Late Professor of Operative and Clinical Surgery in the Medical Department of the University of Wooster, at Cleveland, Ohio. St. Louis, Mo.: J. H. Chambers & Co. 1887.

The scope of this work is sufficiently clear from its title. It is a thick volume of 656 pages, and leaves but little unsaid on the subject of diphtheria. The tables giving the mortality from croup and diphtheria in different countries, will prove very valuable. This work will be of use as a book of reference.

Elements of Botany, including Organography, Vegetable Histology, Vegetable Physiology, and Vegetable Taxonomy, and a Glossary of Botanical Terms. By EDSON S. BASTIN. Chicago: G. P. Engelhardt & Co. 8vo. pp. 282. Figures, 459.

The number of text-books on botany published in this country has become so large, that one wonders who buy them. Practically, they are all much alike in quality, but vary considerably in quantity. The present work is well printed, and, in general, well illustrated, and the author has included nearly all subjects of general botanical interest, which he has reduced to a convenient book-form. The parts which treat of organography, histology, and physiology are good presentations of the subject, well written, easy to read, and more accurate in statement than is generally the case in text-books covering so wide a field. A defect in the book is that the author has attempted to cover too wide a field in too few pages. This is seen in that part of the book relating to the classification of plants, which includes only about fifty pages, and is not so well illustrated as the rest of the book. It seems to us that the reader would hardly get a clear impression of the different divisions of the vegetable kingdom from the condensed account here given, and it would have been better to omit this part of the work, unless the subject could have been treated more *in extenso*. The yeast-plant and its allies may be classed under *protophytes*, but they certainly do not belong to the *schizomycetes*. The statements about the locomotion of *desmids* and *diatoms* are likely to mislead the reader, and the accounts of *myxomycetes* and *ascomycetes* could not be understood by those who are not already well read in the subject. In short, the present "Elements," if we except the part on classification, afford a good text-book for persons who have advanced beyond the stage of beginners.

The introduction of practical exercises at the end of some of the chapters, as is the custom of a good many writers of text-books at the present day, does not seem to us to be worthy of commendation. In the present work, the practical exercises come nearer to being practical than in some works which might be named, but, even here, the practical is not always to be distinguished from what, on the one hand, is so simple as to be superfluous, or, on the other hand, is too complicated to be undertaken without an instructor.

Outlines of the Pathology and Treatment of Syphilis and Allied Venereal Diseases. By HERMANN VON TEISEL, M.D., and MAXIMILIAN VON TEISEL, M. D., translated by H. RAPHAEL, M.D. New York: D. Appleton & Co. 1886.

This is a translation of the well-known work of the Teisels, father and son, upon syphilis, in which the chapters upon syphilitic affections of the eye and of the larynx and trachea are contributed by Professors Mauthner and Schrötter respectively. The book is a valuable one, being the outcome of a large and well used experience, although the views of the author upon the treatment of syphilis differ from those generally accepted, in advocating the so-called expectant method and in the administration of iodine, rather than of mercury, in the earlier stages of the disease, the latter drug being used only when the manifestations persist for a longer period than four months after the first appearance of general symptoms. In case, however, the symptoms become urgent or dangerous at any time, the authors advise the immediate use of mercury, preferably by inunction, fully recognizing the power of this drug to modify and check the progress of the disease. This so called expectant method of treatment is regarded by the authors as the one which yields ultimately the best and most permanent results. It represents one of the extremes in the different opinions with regard to the proper treatment of

syphilis, and is much preferable to its opposite, namely, the precipitate administration of mercury upon the appearance of what is supposed to be an initial lesion or primary sore, a proceeding which should be mentioned only to be condemned. The portions of the work most open to criticism are those in which the complications and sequelæ of gonorrhœa are considered, the chapter upon stricture of the urethra being notably inadequate. The use, also, of such terms as syphilitic acne, syphilitic varicella, etc., is to be deprecated as misleading and improper. The work of the translator is well done and the notes inserted by him are judicious and to the point. G. H. T.

Ligaments, their Nature and Morphology. By JOHN BLAND SUTTON, F.R.C.S. Philadelphia: P. Blakiston, Son & Co. 1887.

This little book, of about one hundred pages, is very interesting, both as a study in anatomy, and as a contribution to evolutionary literature. The author has recently published several papers on the nature of ligaments in the *Journal of Anatomy and Physiology*, and this treatise is a general discussion of the nature of ligaments and fasciæ. It is well known that in different animals we find that the place of what is a ligament in one may be taken by a muscle in another, or that, on the other hand, it may be represented by bone. We know also, that the origin and insertion of muscles, but particularly the former, are apt to vary in different orders. We know also that in the human fœtus we find temporary conditions that correspond to those of the adult in lower animals. It is evident that a knowledge of these facts gives a new interest to dry details of structure. Mr. Sutton brings to the study a good knowledge of comparative anatomy, and has written an interesting and valuable book. One of the most remarkable discussions is that of the significance of the round ligament of the hip-joint. He considers it the separated tendon of the *pectineus*, which is the homologue of the *ambiens* in birds. Now in the remarkable lizard spenodon the tendon of the *ambiens* passes inside the capsule to the head of the femur. In the ostrich the ligament and muscle are continuous. In the horse the ligaments are in two parts, one of which is continuous with the pectineus outside the joint. We have chosen this as a specimen, for it shows alike the learning and ingenuity of the author, and, as it seems to us, the unsatisfactory nature of the explanation. Is the horse nearer to a common ancestor of birds and reptiles than any other mammal? There is much written of degeneration of tissue and of migration of muscles, as if it were possible to trace the steps of these processes. Here and there, to be sure, we see an approach to a demonstration, but demonstrations founded only on special parts of the body are misleading. Here is an instance of remarkable reasoning: "Even the central tendon of the diaphragm has arisen from the metamorphosis of its muscular fibres; for in the porpoise there is no trace of a tendon, but it is muscular in structure throughout the whole of its extent." If we mistake not, the diaphragm is wholly muscular in no mammals except the cetacea, which are usually considered an aberrant branch. Why then should the porpoise be cited as evidence when this condition is not found in less divergent forms? We are aware that Prof. Albrecht holds that the promammalia were very like the cetacea, but he has few followers, and there is nothing to indicate that Mr. Sutton is one of them. If he were, his position would, in this instance, be more logical. While, therefore, we dissent in many instances from Mr. Sutton's arguments, we wish to recommend highly his work, with this reservation. The interest of the intelligent student is roused by such studies, and he obtains a broader view of human anatomy. T. D.

A System of Practical Medicine by American Authors. Edited by WM. PEPPER, M.D., LL.D. Volume V. Diseases of the Nervous System. 8vo. pp. 1326. Philadelphia: Lea Brothers & Co. 1886.

This huge volume forms a fitting close to the great system of medicine which in so short a time has won so high a position in medical literature, and has done such credit to the profession in this country. Among the twenty-three contributors are the names of the leading neurologists in America, and most of the work in the volume is of the highest value. In a very few instances, of course, the articles are mere compilations, but the great majority are filled with the results of personal investigation, as well as of wide reading, and form a most valuable addition to our knowledge.

In common with the preceding volumes, certain great defects of method must be condemned. The first is the utter lack of system employed in the arrangement of the articles, due largely, we suppose, to the wretched classification of diseases adopted. This want of system, moreover, may be the reason for the many omissions we have noted. At any rate the editors have omitted to include any articles on poliomyelitis of adults, progressive ophthalmoplegia, tetany, the acute diseases of the medulla, or the various forms of peripheral spasm and paralysis. A still greater defect, which has injured previous volumes also, is the utter lack of proportion shown in the space assigned to the different articles. Hysteria and its allied conditions occupy a hundred and fifty pages, while the entire subject of mental diseases gets a little over a hundred, and the disorders of speech have less space than facial hemiatrophy.

We regret that we have not space to speak of the individual articles as they deserve. The following is a list of the contributors and their articles:

Dr. E. C. Seguin, "General Semeiology of Diseases of the Nervous System: Data of Diagnosis;" "The Localization of Lesions in the Nervous System." Dr. C. F. Folsom, "Mental Diseases." Dr. C. K. Mills, "Hysteria"; "Hystero-Epilepsy"; "Catalepsy"; "Ecstasy." Dr. H. C. Wood, "Neurasthenia." Dr. H. M. Lyman, "Sleep and its Disorders." Dr. H. C. Wood, "Acute Affections produced by Exposure to Heat." Dr. Wharton Sinkler, "Headache." Dr. S. Weir Mitchell, "Vertigo." Dr. Wharton Sinkler, "Tremor"; "Paralysis Agitans;" "Chorea"; "Athetosis." Dr. A. McL. Hamilton, "Local Convulsive Disorders"; "Epilepsy." Dr. M. J. Lewis, "The Neural Disorders of Writers and Artisans." Dr. P. S. Conner, "Tetanus." Dr. E. P. Davis, "Disorders of Speech." Dr. James C. Wilson, "Alcoholism"; "The Opium Habit and Kindred Affections"; "Chronic Lead-Poisoning." Dr. C. K. Mills, "Progressive Unilateral Facial Atrophy." Dr. Francis Minot, "Diseases of the Membranes of the Brain and Spinal Cord"; "Tubercular Meningitis"; "Chronic Hydrocephalus"; "Congestion, Inflammation, and Hæmorrhage of the Membranes of the Spinal Cord." Dr. John Ashhurst, Jr., "Spina Bifida." Dr.

E. C. Spitzka, "Anæmia and Hyperæmia of the Brain and Spinal Cord"; "The Chronic Inflammatory and Degenerative Affections of the Spinal Cord." Dr. Wm. Hunt, "Concussion of the Brain and Spinal Cord." Dr. R. T. Edes, "Intracranial Hæmorrhage and Occlusion of the Cerebral Vessels, Apoplexy, Softening of the Brain, Cerebral Paralysis." Dr. H. D. Schmidt, "Atrophy and Hypertrophy of the Brain." Dr. H. C. Wood, "Syphilitic Affections of the Nerve-centres." Dr. C. K. Mills and Dr. J. H. Lloyd, "Tumors of the Brain and its Envelopes"; "Tumors of the Spinal Cord and its Envelopes." Dr. Mary Putnam Jacobi, "Infantile Spinal Paralysis." Dr. H. D. Schmidt, "Disease of One Lateral Half of the Spinal Cord"; "Progressive Labio-glosso-laryngeal Paralysis." Dr. F. T. Miles, "Diseases of the Peripheral Nerves." Dr. J. J. Putnam, "Neuralgia." Dr. M. Allen Starr, "Vaso-motor and Trophic Neuroses."

Elements of Physiological Psychology. By GEORGE T. LADD, Professor of Physiology in Yale University. 8vo. pp. xi, 696. 114 illustrations. New York: Charles Scribner's Sons. 1887.

The new Physiological Psychology may fairly be said to have taken as one of its fundamental theses, with the change of a single word, Moleschott's once ridiculed dictum, "*Kein Gedanke ohne Phosphor.*" One of its assertions to-day, accepted by many of its students, is "*Kein Gedanke ohne Hirnsubstanz.*" Prof. Ladd is the first, we believe, who has attempted to present to the English reader a complete review of the entire subject. In the present work he has followed Wundt, whose "*Grundzüge der physiologischen Psychologie,*" has been his guide. Beside Wundt, however, he has been a firm disciple of Lotze.

Such a study of "the effort to approach the phenomena of mind from the experimental and physiological point of view" is, of course, of the utmost interest, and we began the perusal of Prof. Ladd's volume with the highest anticipations. He decries all declamation, and aims to set forth "the assured or alleged results of Physiological Psychology," reserving to himself the right to accept only the results that are assured. Prof. Ladd has also brought to his task a thorough knowledge of nervous physiology, and has prepared himself for his work by a careful and exhaustive examination of the literature of the subject. Nevertheless, we must admit that we closed the volume with a feeling of disappointment. Psychology is not a branch of knowledge that admits of mathematical demonstration, and upon many of the problems of mind, mankind will probably never agree, yet since the phenomena of mind have been approached from the new basis, much has certainly been added to our knowledge. Since the self-contemplation of the metaphysicians has been discarded, and since to the study of the workings of our own consciousness the data afforded by the anatomy and physiology, the development and the pathology of the nervous system have been added, we have been enabled not only to explain on an intelligible basis the simpler actions of the mind, but to resolve the higher actions into their component parts, so as to afford us some idea, vague and fragmentary though it may be, of the processes that are involved in the workings of the mind.

With this new psychology, Prof. Ladd is at variance. He divides his book into three parts; the first dealing with the nervous mechanism, the second with the correlations of the nervous mechanism and the mind, and the third with the nature of the mind. His discussion of the physiology of the nervous system and of the quality of sensation is in every way admirable, and so far he follows the teachings of the modern psychology. At this point, however, he branches off. With some of the modern German philosophers he "has gone back to Kant," in denying the empirical basis of our ideas of time and space, and in claiming that they "can never be regarded otherwise than as due to the constructive and synthetic action of the mind." Feeling is not a form of sensation, but "an original and underived form of consciousness, or mode of the operation of the conscious mind." In regard to consciousness itself, he asks whether its phenomena "require the assumption of one real and non-material being as the subject and ground of them all," and answers his question in the affirmative. "The subject of all the states of consciousness is a real unit being, called mind; which is of non-material nature, and acts and develops according to laws of its own, but is specially correlated with certain material molecules and masses forming the substance of the brain."

Such an assumption at once leads to difficulties. To any one trained in modern science, with the conservation of energy as one of its main tenets, the belief in a non-material something which can act on a material substance is untenable, and yet Prof. Ladd's further statements directly assert that this non-material mind acts on the material brain. "No sensations will arise in the mind unless the brain be affected in a certain way," although "all sensations are modes of the behavior of a being that is non-material and a unit being, and is called mind." The material brain and the non-material mind are mutually dependent in their modes of behavior, yet their connection is not to be found, and the difficulty which arises from the want of such a connection is treated as of no consequence. Yet it is "impossible to avoid speaking of the connection of brain and mind in terms of causation." "The assumption that the mind is a real being, which can be acted upon by the brain, and which can act on the body through the brain, is the only one compatible with all the facts of experience."

Prof. Ladd will admit the teachings of the new psychology only so far as they are thoroughly well-established. He fails to take into his calculations the data afforded by a study of the development and pathology of the mind, and, when asked to push his reasoning further, to resolve the complex processes of mind into their component parts, and to try to explain the unknown in terms of the known, he exclaims that "the theory, standing on a slender basis of real fact, makes a leap into the dark which carries it centuries in advance of where the light of modern research is now clearly shining." He therefore makes a still greater leap which lands him in a metaphysical bog where real fact is altogether lost sight of, and thence he sinks to a concluding chapter of quibbling on the old subject of the idealism of Berkeley that would do credit to the schoolmen.

The high anticipations with which we began the book were not realized, for we closed it with weariness at the incomplete reasoning, the neglect of analysis of the higher mental phenomena, the repeated beggings of the question, and the final descent into the verbal hair-splittings of the metaphysicians.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 21, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

KÖLLIKER'S ADDRESS BEFORE THE GERMAN ANATOMICAL SOCIETY.

WITHIN a year the anatomists of Germany have formed a Society which promises to be an important one. Nearly two hundred members are enrolled, representing many countries, France, Italy, England, Russia and the United States, and we believe others. The first meeting was held at Leipzig on April 14th and 15th. There were many interesting and valuable papers; but the great event of the meeting was the address by the President, Prof. Kölliker, the full text of which has been but recently received. There are probably not many men fitted to speak on anatomy with so much authority and able to take so comprehensive a view of the wide field which includes coarse and minute anatomy, comparative as well as human, anthropology, evolution, or at least a part of it, and the wonderful minute changes in the nuclei of cells. Prof. Kölliker began by speaking of the scattering of anatomical literature through many journals in many languages. The confusion, which is already great, threatens to become greater. He suggests that authors should write for strictly anatomical journals and should write either in German, English, French or Italian.

After this introduction, the speaker took up the theory of descent and treated his audience to a scholarly, dispassionate discussion of the subject viewed from an anatomical standpoint, saying but very little that had any bearing on psychology. The discussion is not, therefore, a complete one, in the widest sense, but as giving the views of a distinguished anatomist on anatomy, one of great weight. He began by calling attention to the fact that apart from numberless shades of individual opinions there are two great schools of evolutionists. The first, and from their noisy assertions one would think the only one in England and America, is that which believes in gradual changes from external causes and clings to the belief that acquired peculiarities can be inherited. The other school, to which Kölliker himself belongs, believes in sudden changes from internal causes. The gulf between these two views is so great that it can hardly be bridged over. Kölliker, though evidently firm in his convictions, admits that no one can foretell the result, and that as yet neither theory is established. His whole tone is in most refreshing contrast to that of the followers of Haeckel, who with what some must regard as extreme dogmatism insist on their theories being accepted as beyond question. The great difficulty in Darwinism proper of accounting for the want of intermediate types, disappears if sudden changes are admitted. Kölliker replies to Weisman's criticism that the sudden change theory in no way accounts for the fitness of animals for their environment, by pointing out that animals like the butterfly and the frog, which change rapidly from very different forms, are none the less well adapted to their surroundings. His own words are worth quoting: "The hypothesis of a development, from internal causes, of organisms which progress with greater or smaller leaps in a definite direction upward is indeed not proved. It rests, however, on a series of undoubted facts, as on the ontogenesis of the higher organisms which run with a set of leaps through lower forms, as is shown most clearly in the cases of metamorphosis, and which therefore brings more in support of what occurs than Darwin's theory which has as yet in no single instance furnished a probable explanation of great changes."

This discussion naturally led to that of heredity, of the transmission of acquired peculiarities and as to what is meant by an internal cause, as opposed to external ones. Kölliker rejects the commonly received opinion that acquired peculiarities are inherited and is opposed in this matter to no less a man than Virchow. Now the question arises what is meant by "acquired?" If we say that it implies an external cause we seem to have a pretty fair definition, but Virchow considers the action of the spermatozoon on the ovum as an external cause.

Kölliker disputes this and puts his points strongly. The earliest beginning of the embryo contains the male as well as the female element. The action of one might be called an external cause as well as that of the other. The child inherits from the father as well as from the mother. He concludes, however, that there is no great difference between his views and those of Virchow, provided the latter be willing to call "internal" all causes proceeding from the impregnated ovum. Several other anatomical questions are lightly touched but not dwelt upon, as Kölliker naturally reserved space for histology. He takes up, to tear to pieces, Heitzmann's theory that bodies do not consist of separate elements but are conglomerate multinuclear masses of which the elements join one another. This has been advanced as destroying Schwann's cell doctrine, but according to Kölliker what is true in it is not new and what is new does not bear examination. Space does not allow us to consider this point at length, nor more than to mention that the next topic was the structure of the cell and

the process of division. At length the speaker came to anthropology, and he expressed himself as quite agreed with Virchow that the "missing link" is not likely to be found, and further that the relations of the various human families to one another are by no means settled. Kölliker points out that after all, those who take his view of evolution, namely, that of sudden changes, have no "missing link" to search for. We were surprised to find that Kölliker thinks that the human race need not have had a common ancestor but that different portions may have appeared independently. This seems to us a departure from the caution that is characteristic of the address as a whole. Even if an analogy could be established, as some believe, in the origin of important organs, it gives no warrant for such a generalization.

The address is an important one, for it shows the state of many questions, at least the anatomical side of them, with great clearness, which is of no small value in the confusion that results from vague discussions and bitter partisanship.

REPORT OF THE ENGLISH COMMITTEE OF INQUIRY INTO PASTEUR'S TREATMENT OF HYDROPHOBIA.

IN April, 1886, a committee was appointed by the President of the Local Government Board (England), to inquire into Pasteur's treatment of hydrophobia. The report was recently presented to Parliament, and abstracts of its important features are furnished by the late English medical journals. The report is signed by James Paget (chairman), T. Lauder Brunton, George Fleming, Joseph Lister, Richard Quain, Henry E. Roscoe, J. Burdon Sanderson, and Victor Horsley, secretary; names which will be immediately recognized as making a very strong committee for the purpose for which it was appointed. The conclusions of such a committee, especially if of a positive character, as they are in this instance, should, and undoubtedly will, go far to dispel the doubts which were beginning to find more frequent expression as to the value of the reports of the cases treated at the Pasteur Institute and the reliability and safety of Pasteur's method of preventive inoculation against hydrophobia.

Three members of the committee, besides the secretary, Messrs. Roscoe, Lauder Brunton, and Burdon Sanderson, studied the process and its results in Paris, where the method of treatment was observed. Information was obtained from Pasteur himself, and by his courtesy a personal investigation was made of ninety cases inoculated by him, these being mostly those which had been earliest treated, those in which the periods since inoculation were longest, and those living in or within easy reach of Paris.

Mr. Horsley, the secretary, subsequently made a careful series of experiments as to the effects of the method of inoculations upon the lower animals.

As the final stage of the inquiry the results of the investigation in Paris and of the experiments by Mr. Horsley were submitted to the remaining members of the committee, Messrs. Paget, Lister, Quain and Fleming, for a critical examination.

Mr. Horsley's experiments were regarded as entirely confirming M. Pasteur's discovery of a method by which healthy animals may be protected from the infection of rabies, a method of protection comparable with that which vaccination affords against infection from small-pox. The duration of the immunity conferred by this inoculation is not yet determined, but during the two years that have passed since it was first proved, there have been no indications of its being limited. The importance of this discovery, whether for its practical utility or for its application in general pathology, the committee considers that it would be impossible to overestimate.

The committee also thinks it certain that the inoculations practised by Pasteur have prevented the occurrence of hydrophobia in a large proportion of those who, if they had not been so inoculated, would have died of that disease, and furthermore, his discovery shows that it may become possible to arrest, by inoculation, even after infection, other diseases besides hydrophobia. Up to the end of 1886, of two hundred and thirty-three persons bitten by animals in which rabies was *proved*, and subsequently inoculated, only four died, whereas ordinarily without inoculation, forty should have died. Between the end of last December and the end of March, Pasteur inoculated five hundred and nine persons bitten by animals *proved* to have been rabid; of these only two have died, one of whom, bitten by a wolf a month before inoculation, died after only three days treatment.

As another result Pasteur's researches have supplied a sure means of determining whether an animal which has died under suspicion of rabies was really affected with that disease or not.

In regard to the dangers from inoculation the committee concluded that there is no evidence or probability of any danger to health at all, from the first or usual method, but after the *intensive* method, which has been practised only in the most urgent cases and has since its first trial been modified, deaths have occurred which might possibly be attributed to the inoculation rather than to the original infection.

From the consideration of Pasteur's work in the past, the committee passes on to the question whether rabies or hydrophobia can be prevented in the future in England, and the committee evidently believes in the desirability of establishing a Pasteur Institute in England, though a regard to official usages apparently forbade its making such a recommendation in formal terms.

An appendix is added to the report, containing (1) an abstract report of Mr. Horsley's experiments; (2) a report on persons in France examined by members of the committee with a list of English persons treated at the Pasteur Institute from January, 1886, to January, 1887; (3) an account of Pasteur's methods of preventive inoculation. The whole forms undoubtedly the strongest and most convincing endorsement which

Pasteur's methods and results have yet received, an endorsement which, in the absence of fuller details emanating from him, was much needed.

THE TEACHING OF TEMPERANCE BY MANIKINS.

IN an age when the gravest forms of epilepsy are cured by tenotomy of a rectus oculi muscle; when insanity, hysteria, and neuralgia are remedied by hypnotic passes, and patients with anæsthesia, monoplegia and paraplegia are restored by plates of gold, copper, and even india rubber, it is not surprising that short and easy methods of inculcating habits of virtue, sobriety and temperance should have occurred to certain clever men of genius whose supreme *end* (to put the matter in a right shape), is the promotion of morals, whose *means* is the making of a little money.

Our State legislators have wisely decreed that the youngest as well as the oldest of the pupils in the public schools shall be taught the physiological and pathological effects of strong drink and tobacco. Gray headed, wise men in the pedagogic profession shook their heads and said: "the question is one of complexity and difficulty"; but the friendly artist comes to their aid and says: "It is perfectly easy — do you see this picture? This is the stomach of a total abstinence man. How pale it looks! Now just look at this fiery red stomach. This is the effect of one glass of grog. Take two and you will have a stomach like this — see these diphtheritic patches, and this slate-colored appearance. But if you keep on drinking you will have a stomach like this: see these ghastly-looking ulcers! And here is a healthy heart, and here is a *tobacco heart!* See how puckered it looks, and all the blood is squeezed out of it. And here are the tobacco kidneys all bathed in pus!"

No one can doubt that such an object lesson as this will make a deep and lasting impression on the dullest and most obdurate scholar. This is a truly fortunate age in which we live; and when we think of the risks previous generations have encountered, and the temptations to which they have been subjected we can but wonder that they have made any — even a *poor* advancement — without the aids to sobriety and virtue which are now available to the youngest and poorest juvenile pupils of our public schools, owing to the far-seeing prudence and liberality of our school committees.

Who would consent again to tread the slippery paths of youth without the guiding help of a manikin?

MEDICAL NOTES.

— At a meeting of the Hospital Medical Society of Paris, M. Ferrol brought up the case of a patient, aged fifty-six, suffering from cancer of the stomach, in whom the subclavicular glands were infiltrated. This is his fourth case in which he has noted the enlargement of the subclavicular glands in this disease.

— It should not be forgotten that the late Professor Mark Hopkins, one of the foremost thinkers and teachers in philosophy of his generation, was a regularly graduated doctor of medicine. He took his degree in medicine in New York, in 1829, and sought to form a business partnership with an older practitioner in Binghamptom, N. Y. Failing in this aim, he was after three months called permanently away from the practice of medicine, by accepting an invitation to the chair of Rhetoric and Moral Philosophy in Williams College, with which institution he remained identified as professor and as president during his long and active life.

—The Paris correspondent of the *Philadelphia Medical Times* says that considerable comment has been made in that city on a phrase in a letter that Billroth, of Vienna, has written in one of the newspapers there. Speaking of Pasteur's work, he said, "Well, we don't blame the French for applauding so much Pasteur's discovery, for not only have they not made any great progress in science these last twenty years, but they are following with difficulty and halting steps the colossal progress of German and English science." To put it mildly, this way of talking by the great Vienna surgeon has caused a great deal of irritation in Paris, says the writer, and Herr Billroth is curtly reminded that he and others are much indebted for their education to such men as the illustrious dead French surgeons were, not to mention the ones now living. They also ask him what sort of a man in neuropathology Germany can present in the last twenty years to compare with Duchenne (of Boulogne), Vulpian, Charcot, etc., or in physiology with Magendie, Flourens, Longet, Bernard, P. Bert, Brown-Séquard, etc.

— Cholera is reported as very active in Catania, Sicily.

BOSTON.

— Dr. Henry J. Bigelow, our readers will be glad to learn, is rapidly recovering his health after an illness which had lasted some weeks and caused much anxiety to his friends.

— During the past week whilst most of the United States have been suffering from a more than torrid atmosphere, the thermometer in many places rising well above 100° F., and the death-rate in some cities, among the very young and those exposed to the sun, reaching truly epidemic proportions, in eastern New England the temperature has not risen above the eighties, and the air has been fresh and pleasant.

NEW YORK.

— A case of death from an over-dose of chloral was reported last week. The victim had been using the drug for insomnia for about a year, and some six months ago came very near dying from the effects of an unusually large dose.

— Dr. Jared Linsley, one of the most venerable and highly respected physicians of New York, died at the family homestead as Northford, Conn., on July 12.

He was born at this place in 1803, and graduated at Yale College in 1826. He received his medical degree from the College of Physicians and Surgeons, New York, and at the time of his death was one of the trustees of this institution. Dr. Linsley had a large and lucrative practice, and was always noted for his kindness of disposition and many generous benefactions.

— Mr. Martin, of the Columbia College School of Mines, who has been making an examination of some of the ice cream which made a number of persons ill on the Fourth of July, reports that the specimens sent him were too small to furnish unmistakable evidence of tyrotoxicon; but his investigations indicate that the cream employed was stale at the time it was used, so that fermentation had begun when the ice cream was made. This was arrested by the process of freezing, but no doubt commenced again in the stomach of those eating the ice cream, and thus gave rise to the sickness.

— On July 9, the summer corps of physicians to visit the tenement districts was organized by the Board of Health. Thirty-seven medical men, being the entire list received from the Civil Service Examining Board as eligible for positions, were appointed, and the number will be increased to fifty as soon as practicable. This extra service, which had been maintained during the heated term for a number of years, and which is now resumed, had to be discontinued last year, it will be remembered, on account of the failure of the authorities to make the requisite appropriation for its support. Special pains will be taken to make the service more efficient than ever during the present season, and Dr. Moreau Morris of the Health Department has been designated to take charge of the work of the corps. Careful instructions will be given the visiting physicians by the President of the Board of Health, Mr. Bayles, by Commissioner Bryant, by Sanitary Superintendent Day, and by Dr. J. B. Taylor. The latter has charge of the department of contagious diseases, and the effort will be made to ferret out and report every case of this kind among the tenement population. The members of the corps have been informed that the policy of the Board of Health will be to give the preference in appointments next year to those who do the best work this summer, and that they will also be preferred over new men in permanent appointments in the department when vacancies occur. The Board of Health has asked the coöperation of the various dispensaries in the city in the work of the corps in furnishing medicines to those too poor to purchase them on the prescription of the physicians belonging to it.

— The large mortality from contagious diseases which has prevailed during the present year has recently been the subject of considerable discussion by the Board of Health, and since the appointment of Dr. Bryant as Health Commissioner, steps have been taken which it is hoped will materially reduce the number of cases and deaths in the future. Up to the present time only cases of small-pox and typhus fever have been removed to hospital; but it has now been determined, on account of the danger to the public health, to treat in the same manner all cases of diphtheria, scarlet fever, measles, and other contagious diseases which cannot be properly isolated at home. Preparations have already been begun at the Willard Parker Hospital, at the foot of East Sixteenth Street, for the reception of those suffering from such affections, and the attention of the Board of Education has been called to the danger likely to arise from permitting janitors' families to reside in the public school buildings, on account of the possibility of infection in the event of contagious disease occurring among them.

— Dr. Taylor, of the bureau of Contagious Diseases, reports that since January 1st, there has been 1,132 deaths from diphtheria, 663 from measles, and 246 from scarlet fever, and in his opinion the prevalence of these diseases is due in a great measure to the ignorance of the tenement-house population in regard to their dangerous character and their gross carelessness in the matter of the necessary precautions for preventing the spread of such contagious affections. Special care will also be taken that there is no improper exposure of those who die, that well persons are not exposed to contagion at wakes or public funerals, and that clothing, bedding, and premises are promptly and thoroughly disinfected. There are several new pavilions at North Brother Island which it is proposed to set apart for convalescents, and, by thus removing those able to go, sufficient room will be secured for the accommodation of acute cases at the Willard Parker Hospital.

Miscellany.

INJURIES OF BASE BALL PLAYERS.

Dr. A. H. P. Leuf, writes a timely article in the *Medical and Surgical Reporter* on the above subject, of which he speaks from personal knowledge both as a physician and as a participant in the game. Among the other injuries spoken of are the subluxations so commonly met with. On this point the author says: "I have a finger on my right hand which presents one of these thickenings. It was derived from five successive injuries received at the same place within one week while I was serving an apprenticeship to the game. It was treated *secundum artem*. The result was bad. Every one of the other nine fingers have been injured since, and some as badly as the specimen mentioned, but to-day they are perfectly normal. They were not treated according to the "best surgical methods," but according to base-ball custom. This consisted in continuing to play, and, whenever opportunity offered, either in the street, in the office, on cars, or upon the field, in firmly grasping the finger at about the middle and rubbing towards the tip. If continued a little while, the swelling, stiffness and soreness diminish and after some weeks are entirely gone."

Compound dislocations, while not common, have been observed by the writer to do well when simply pulled into place and bandaged moderately tight. Playing in each instance was continued the very next day or after a few days rest at most. Primary union was the rule.

In the treatment of base-ball injuries, great stress is laid by the writer on hot water. "Nothing else," he says, "compares with it. Its effects in the relief of pain are almost instantaneous. It is easily applied, and inexpensive. To be effective, the water must be hot as can be borne, and it must be kept so for an hour at a time if possible. The most marked swelling of the hands and severe pain can thus be reduced within twenty minutes. Otherwise it would require hours and be accompanied by some suffering. I have repeatedly observed that nothing will do so much harm to a player as to have him abstain altogether from playing because he has some trivial injury or sore muscles. No other treatment should be attempted for subluxation and simple dislocations without at first liberally using hot water. After this, it is best to surround the injured member with adhesive plaster and to place over all a moderately firm finger-bandage. The player may then continue playing if he choose."

THE PUPIL IN ITS SEMEIOLOGICAL ASPECT.

IN an interesting paper in the July number of *The American Journal of Medical Sciences*, Mr. William Macewen, of Glasgow, gives a brief outline of the physiological phenomenon pertaining to the movements of the pupil, and then presents a series of personal observations. He cites evidence to show that the suspension or abolition of cerebral function in the living body is attended by mydriasis, the latter being the sequent of the former. If inquiry be made concerning the mechanism inducing this pupillary effect coincident with the arrest of cerebral function, the theory which explains the greater part, if not the whole of the phenomena, is that which has been so ably advocated by Mosso. The passive movements of the pupil are regulated by the vascular system of the iris, which is in complete harmony with that of the encephalon. In these conditions inducing general suspension of the cerebral function, a state of ischæmia pervails in the brain and iris inducing mydriasis. This, likewise, obtains in unilateral lesions, where the pressure is so great as to induce anæmia of brain and iris. Myosis may also be brought about by a like mechanism acting in the opposite direction. The "irritation" setting up congestion of the cerebral and meningeal vessels, leads to congestion of the vessels of the iris, and so produces contraction of the pupil.

Dr. Macewen shows that when the function of the brain is in abeyance the pupils are in a state of stabile mydriasis.

When the function of the brain is interfered with by conditions usually included under the term "irritation," the pupils are in a state of myosis, sometimes labile, but generally stabile myosis.

The same pathological factors which cause myosis may also cause mydriasis, the degree in which these factors are present being the determining point between the former and the latter, and not merely the particular locus in the brain.

When the function of one-half of the cerebrum is placed in abeyance by a superficial or cortical lesion, the pupil on the same side as the lesion is in a state of stabile mydriasis.

When the functions of one-half the cerebrum is interfered with by some source of cortical irritation, the pupil on the corresponding side to the lesion is in a state of myosis.

Hæmorrhage into the pons Varolii when strong causes strongly contracted pupils; but when it is more extensive, involving the gray matter beneath the aqueduct of Sylvius, a state of stabile mydriasis is induced.

Dr. Macewen concludes by pointing out the conditions under which myosis and mydriasis occur.

DILATATION OF THE RIGHT VENTRICLE, AND ITS EXPLORATORY PUNCTURE.

PROFESSOR Schrötter describes in the *Med. Jahrbücher* (Vienna), 1887, Heft, 1, and *London Medical Record* June 15, a case of the above mentioned lesions treated by exploratory puncture. The patient, a girl, aged 14, had always suffered from severe palpitation and breathlessness, and presented the following signs. The face and extremities were very cyanotic; the cervical veins showed distinct systolic pulsations. Right side of thorax in front projects more than left. Respiration, 26. Apex-beat of heart not visible anywhere, but palpable in the left sixth intercostal space, just outside the nipple-line. The cardiac dulness began just internal to the apex-beat, and reached horizontally across the lower end of the sternum to the right nipple-line. On the left side it extended upwards to the lower border of the fourth rib, half way between the nipple and sternal lines; on the right side it reached as high as the lower edge of the third rib, and at the level of the fourth rib reached outwards almost to the nipple-line, whilst a little lower it became continuous with the mammary line as far as the sixth rib. On auscultation, a double murmur was heard at the heart's apex, less distinct at the base, where the second pulmonary sound was accentuated.

On auscultation, vesicular breathing on both sides, with medium crepitations, and a few rhonchi. There were evidently mitral insufficiency and stenosis, together with tricuspid insufficiency. But how was the peculiar form of the cardiac dulness to be explained? Was it due to a pericardial or to a circumscribed pleuritic exudation, or to extreme distension of the right ventricles? As the cyanosis and dyspnœa increased, an exploratory puncture was made with the needle of a Pravaz' syringe. Pure blood escaped, as was expected. (Professor Schrötter has already advocated the puncture of aortic aneurysms in certain cases — *see* Ueber Therapie der Aorten aneurysmen, *Deutsche Archiv. für Klin. Med.*, 1884, Band vi.— and was convinced that the operation was not dangerous.) The operation had no appreciable effect upon the patient, who died nearly three weeks afterwards. The autopsy made by Professor Kundrat showed that the right ventricle was enormously distended. The right lung presented adhesions at the edge and outer surface of the upper and middle lobes. This accounted for the fact that inspiration had made no difference in the cardiac dulness, and also for the

peculiar shape of the latter. The valvular lesions were found to exist as diagnosed. No trace of the exploratory puncture could be seen.

Correspondence.

PREMATURE DISCHARGE OF AMNIOTIC FLUID.

MILTON, N. H., July 16, 1887.

MR. EDITOR,— Perhaps the following case of Clinical Obstetrics may be of interest to some of your more inexperienced readers like myself.

Mrs. P., menstruated last about October 15th, 1886. I was called to see her at 10 o'clock, May 15th, 1887. I found the nurse there and the patient in bed. I learned the following facts:

At about 4 o'clock she got up and passed water, went to bed and slept. She was soon awakened by a large gush of water, which she thought came from "the breaking of the waters." After this she had a few slight pains which ceased before my arrival.

Digital examination showed the head presenting, low down in the pelvis, the os dilated to the size of a half-dollar, the vagina covered with a fluid containing floculi like the vernix caseosa. She was up next day, and in a few days felt better than before.

On July 13th, she had an unnaturally short labor, the waters breaking just before the birth of the head. Between May 15th and July 13th, she had no abnormal symptoms.

Yours truly,

C. D. JONES, M.D., (Harvard 1885).

REPORTED MORTALITY FOR THE WEEK ENDING JULY 11, 1887.

Deaths reported 3,268: under five years of age 1517; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1,201, consumption 270, acute lung diseases 133, diarrhœal diseases 979, diphtheria and croup 66, measles 31, typhoid fever 32, cerebro-spinal meningitis 23, scarlet fever 21, whooping-cough 21, malarial fever 17, erysipelas six, puerperal fever three, small-pox (New York) three. From measles, Boston nine, Philadelphia seven, New York five, Baltimore and Cambridge two each, Milwaukee, Nashville, Charleston, New Bedford, Chelsea, and Malden one each. From cerebro-spinal meningitis, New York four, Boston three, Baltimore, Milwaukee, Nashville, Lowell, New Bedford and Brockton two each, Philadelphia, Worcester, Fall River and Holyoke one each. From scarlet fever New York nine, Philadelphia eight, Pittsburgh one. From whooping-cough, New York seven, Philadelphia five, Boston four, Pittsburgh two, Baltimore, Milwaukee, and Fall River one each. From malarial fever, New York nine, New Orleans three, Philadelphia and Baltimore two each, District of Columbia one. From erysipelas, New York, three, Baltimore, Pittsburgh and Worcester one each. From puerperal fever, Pittsburgh two, New York one.

In the 19 cities and greater towns of Massachusetts, with a population of 937,510 (population of the State 1,941,465) the total death-rate for the week was 27.12 against 21.77 and 20.50 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending June 25th, the death-rate was 17.6. Deaths reported 3,115: infants under one year of age 741; acute diseases of the respiratory organs (London,) 184, measles 213, whooping-cough 127, diarrhœa 69, scarlet fever 43, diphtheria 31, fever 29.

The death-rates ranged from 7.2 in Halifax to 30.1 in Preston; Birkenhead 18.7; Birmingham 13.6; Hull 13.0; Leeds 18.6; Leicester 16.4; Liverpool 22.0; London 15.9; Manchester 26.8; Nottingham 13.3; Sheffield 19.0; Sunderland 14.9.

In Edinburgh 19.0; Glasgow 20.6; Dublin 27.6.

The meteorological record for the week ending July 9, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, July 9, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 9, 1887, TO JULY 15, 1887.

HEGER, A., lieutenant colonel and surgeon. Ordered to Fort Columbus, N. Y. H.

JANEWAY, J. H., major and surgeon. Ordered to Benicia Barracks, as post surgeon, also as attending surgeon at Benicia Arsenal, Cal.

BIRMINGHAM, H. P., captain and assistant surgeon. Ordered to Fort Myer, Va.

WOODRUFF, C. E., first lieutenant and assistant surgeon. Ordered to Fort Mackinas, Mich.

WINNE, C. K., captain and assistant surgeon. Ordered to Fort Wadsworth, N. Y. H.

HAVARD, VALERY, captain and assistant surgeon. Ordered to Fort A. Lincoln, D. T.

MAUS, L. M., captain and assistant surgeon. Ordered to Fort Schuyler, N. Y. H.

GIRARD, J. B., captain and assistant surgeon. Ordered to Fort Lowell, Ariz.

POINDEXTER, J. D., first lieutenant and assistant surgeon. Ordered to Camp Poplar River, M. T.

MACAULEY, C. N. B., first lieutenant and assistant surgeon. Ordered to Fort Gibson, Ind. T.

BYRNE, C. B., captain and assistant surgeon. Ordered to Washington Barracks, D. C.

WILCOX, T. E., captain and assistant surgeon. Ordered to Fort Niobrara, Neb.

LIPPINCOTT, H., major and surgeon. Ordered to Fort Union, N. M.

CLEARY, P. J. A., major and surgeon. Ordered to Fort D. A. Russell, Wyo.

CALDWELL, D. G., major and surgeon. Ordered to Fort Assinniboine, M. T.

TORNEY, G. H., captain and assistant surgeon. Ordered to Fort Robinson, Neb.

REED, WALTER, captain and assistant surgeon. Ordered to Mount Vernon Barracks, Ala.

PATZKI, J. H., captain and assistant surgeon. Ordered to Fort Huachuca, A. T.

EBERT, R. G., captain and assistant surgeon. Ordered to Fort Custer, M. T.

PILCHER, J. E., first lieutenant and assistant surgeon. Ordered to Fort Monroe, Va.

GARDINER, J. DE B. W., captain and assistant surgeon. Ordered to Fort Washakie, Wyo. T.

CHAPIN, A. R., first lieutenant and assistant surgeon. Ordered to Newport Barracks, Ky.

FORWOOD, W. H., major and surgeon. Ordered to Fort Snelling, Minn.

PERLEY, H. O., captain and assistant surgeon. Ordered to Fort Wayne, Mich. S. O. 156, A. G. O., July 8, 1887.

S. O 159, par. 2, A. G. O., July 12, 1887. Assigned Captain W. Matthews, assistant surgeon, as member of Army Retiring Board at Washington, D. C., and relieves Captain J. O. Skinner, assistant surgeon.

EBERT, R. G., captain and assistant surgeon. Will, in changing station from Fort Hamilton, N. Y. H., to Fort Custer, Mont., accompany the 12th Infantry from Department East to Department of Dakota. S. O. 159, A. G. O., July 12, 1887.

MAUS, L. M., and PERLEY, H. O., captains and assistant surgeons. Ordered to accompany the 11th Infantry in changing station from Department Dakota to Department East. S. O. 158, A. G. O., July 11, 1887.

GARDINER, E. F., captain and assistant surgeon. Ordered to accompany the 12th Infantry from Madison Barracks to Duluth, and to return with 11th Infantry. S. O. 143, Division of the Atlantic, July 13, 1887.

WALKER, F. V., first lieutenant and assistant surgeon. Granted leave of absence for four months. S. O. 160, A. G. O., July 13, 1887.

CABELL, JULIAN M., first lieutenant and assistant surgeon. Ordered for duty as medical officer at Department Rifle Camp, near Bellevue, Neb., August 1st, next. S. O. 66, Department Platte, July 8, 1887.

A board of medical officers to consist of Major J. S. Billings, Surgeon; Captain W. Matthews, Assistant Surgeon; Captain F. C. Ainsworth, Assistant Surgeon, is constituted to meet in this city for the examination of a candidate for admission to the Medical Corps of the Army. S. O. 157, A. G. O., July 9, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING JULY 16, 1887.

LONG, W. H., surgeon. Granted leave of absence for thirty days on account of sickness, July 12, 1887.

AUSTIN, H. W., surgeon. Granted leave of absence for thirty days, July 16, 1887.

WATKINS, R. B., assistant surgeon. Relieved from duty at Marine Hospital, Detroit, Mich.; ordered to assume charge of Service at Evansville, Ind., July 9, 1887.

DEATH.

Died at Nantucket, July 9, 1887, John Sullivan Bogg, M.D., M.M.S.S., of Springfield, aged thirty-eight years.

ON THE FREQUENCY WITH WHICH LEAD IS FOUND IN THE URINE, AND ON CERTAIN POINTS IN THE SYMPTOMATOLOGY OF CHRONIC LEAD POISONING.[1]

BY JAMES J. PUTNAM, M.D.

For a number of years past, several of my colleagues and myself have had the urine of patients with a variety of obscure diseases of the nervous system examined for lead, and have been surprised at the frequency with which it has been found to be present.

Wishing to learn whether this occurred only in certain classes of cases, or in the healthy and the sick alike, I have tried of late, with the valuable aid of Professor E. S. Wood, and of Dr. A. M. Comey, of Harvard University, to have these analyses made in a more or less routine fashion, though still giving prominence to the cases in which I had first found lead the most frequently.

The whole number of urine-analyses on which I have to report is eighty-six. In none of these cases were the classical symptoms of lead poisoning, such as colic, marked cachexia, characteristic cerebral attacks, characteristic paralysis, blue-line on the gums, unequivocally present. Twenty-six of the cases have been reported in two previous communications,[2] but are here re-analyzed. All of these patients took five or ten grains of potassic iodide three times daily for four or five days, and then collected a quart of urine, which was acidified with a little acetic acid and sent for examination.

The cases may be divided, for convenience of analysis, into the following groups:

Description.	Cases.	Lead.	
		Present	Absent.
1. No symptoms not attributable to other causes.	11	2	9
2. Neurasthenia and simple depression.	9	5	4
3. Fine muscular tremor; nervous debility.	9	9	0
4. Chronic multiple neuritis; neuritis with chronic myelitis; spastic paraplegia; multiple sclerosis.	19	15	4
5. Vague neuralgias of long standing, probably due in part to neuritis.	4	4	0
6. Locomotor ataxia.	3	0	3
7. Progressive muscular atrophy.	4	0	4
8. Acute poliomyelitis of adult.	1	0	1
9. Cerebral and cerebro-spinal cases.	7	6	1
10. Epilepsy.	8	3	5
11. Sciatica.	2	0	2
12. Profound anæmia, with functional and organic nervous symptoms probably due to that cause.	3	1	2
13. Unclassified.	6	3	3
	86	48	38

Before proceeding to examine these groups in greater detail, I wish to call attention to the character of the evidence and the degree of accuracy, to be expected in an investigation of this kind.

It is well known that we are all taking in small quantities of lead, in our food and our drink, the articles we handle, and even in clothes we wear, and through the matches with which we are liable to light our pipes. It might be maintained as probable that, in view of the fact that lead enters readily into stable compounds with the albuminoid tissues of the body, we all carry about with us more or less of the poison,[3] and yet do not often suffer from its presence.

This conservative view is a wholesome one, and places the burden of proof, with justice, upon the shoulders of the observer who lays new groups of symptoms at the door of chronic poisoning from lead. This makes it important that the observations of many persons should be compared and combined before definite conclusions are drawn, and the present series of cases is offered only as a guide to further inquiry. The method of chemical analysis used in these analyses and first devised in its present form by Professor Wood,[4] is as follows: —

The urine is first evaporated to dryness, then fused in a crucible, with the addition of a little pure nitre, till it becomes white. The crucible is then cooled, and dilute HCl added, hot, to extract the residue after ignition. It is then filtered, and the filtrate treated with ammonia to alkaline reaction, to precipitate the phosphates and iron. Sulphide of ammonium is added at the same time, which throws down the sulphide of iron and lead. This is washed three times by decantation with hot water, then water is added, and the whole acidified with HCl, and allowed to stand until the next day. It is then filtered through a small filter and the residue washed. A little pure (free from iron) nitric acid is then added, drop by drop, by which the sulphide of lead, if present, is dissolved and carried through as nitrate of lead. This is collected in a watch glass, evaporated to dryness, and the final test made by the addition of a drop of water and a crystal of iodide of potassium. Finally, to eliminate bismuth, the iodide of lead is again dissolved in water, and re-precipitated in a test-tube with dilute sulphuric acid. The test-tube is allowed to stand twenty-four hours, and is then twirled gently between the fingers. The sulphate of lead, if present, rises in a delicate spiral.

Dr. Wood believes that this method is exceedingly delicate, and his opinion is borne out by the frequency with which lead has been found when not expected, and by the fact that he has rarely failed to find lead in cases of undoubted poisoning, which is by no means the experience of every investigator.

Such cases do, however, occasionally occur, under this as under all the other methods, and a negative analysis of the urine, especially a single analysis, is not a certain proof that the metal is really absent from the body.

Of the whole number of (eighty-six) cases, lead was found in the urine in forty-eight; in thirty-eight it was not found. If, for the sake of determining more accurately to what extent the presence of the lead is due to an exposure no greater than that to which the whole community is liable, we strike out those cases where the patients, through their profession, or some evident source of poisoning, were known to have been unusually exposed, we have left thirty-two cases in which lead was found, to be compared with thirty-eight where it was not found. We must conclude, so far as these figures are a guide, that, at the outside, in not more than fifty per cent. of persons living in the community at large, can lead be detected in the urine.

It may, of course, be argued, as indicated above, that the failure to find lead still more often probably

[1] Read before the Association of Physicians and Pathologists, June, 1887.

[2] Boston Medical and Surgical Journal, 1883, CIX, No. 2. Journal of Nervous and Mental Disease, 1887, XIV.

[3] See a terse and characteristic report made by Dr. Jacob Bigelow to the Boston Society for Medical Improvement in 1852.

[4] See the Boston Medical and Surgical Journal, Oct. 4, 1883, CIX, page 316.

shows only that the process is imperfect, but it is also to be borne in mind, as affecting this question, that although all persons are doubtless exposed to lead, some persons may eliminate the poison more rapidly and completely than others.

The obvious solution of this question would be furnished by chemical analysis of the organs of persons not presenting symptoms characteristic of lead-poisoning. So far as I know this has never been systematically done, but the following bit of evidence from Dr. Thomas Stevenson, of Guy's Hospital, is worth quoting.[5]

"It has been recently stated by M. Armand Gautier, that ordinary persons take lead to the extent of at least $\frac{1}{150}$ grains daily in their food. My own extensive experience leads me to the conclusion that it is exceptional to find a trace of lead in the body, except in cases of lead-poisoning, but that, on the other hand, it is equally exceptional not to find traces of copper in the human body after death."

Dr. W. B. Hills, assistant professor of chemistry at Harvard Medical College, has also told me that in making analyses of the human tissues he had often found copper but had never happened to find lead. He thinks, however, this may indicate only that lead is present in minute quantities, not that it is absent.

To turn now to the special groups of cases, the *first group* (those in which no symptoms were present which could not be fairly attributed to other causes than lead), contains eleven cases.

Of these eleven cases, three were of persons in perfect health; two were cases of sciatica; one a case of muscular atrophy not characteristic of lead, and affecting but one arm; one was a case of acute localized neuritis; three presented vague symptoms of no especial importance; one was a case of abdominal sarcoma. I will also mention that Dr. Comey examined four samples of his own urine, though without taking potassic iodide, and found no lead.

In two of these cases lead was found, in nine it was absent. This group is obviously too small to be of much statistical value, and the history of at least one of the cases where lead was found, which was that of a patient with abdominal tumor, but of excellent previous health, makes it more than probable that that others of like kind could be found on longer search.

The number of cases in this group might be somewhat increased if we should include in it those now set down in groups two and nine, of chronic functional nervous diseases, the neurasthenias and the epilepsies, which are those which could be with the least probability attributed to lead. If we do this, we raise the number of cases with no characteristic symptoms to twenty-eight, in ten of which lead was found. This gives us a provisional proportion of one to three as indicating the probable frequency of occurrence of lead in discoverable quantities without causing signs of disease.

If we add still further to this first group, the third group, characterized by symptoms of debility, such as might be due to many causes, but also by slight muscular tremor, recurrent paræsthesia of the hands, and other symptoms pointing possibly to slight organic disease, we get thirty-seven cases, in nineteen of which lead was found. In other words, we come back to the original proportion of fifty per cent. in favor of lead in healthy persons, which is, I think, undoubtedly too large.

[5] Guy's Hospital Reports, 1882, xxvi, p. 483.

In the *second group of cases*, a variety of neurasthenic and mild mental symptoms were present, without marked signs of nutritive disease, local or general. This group comprises nine cases, in five of which lead was found, while in four it was absent.

The cases are not sufficiently alike to form a coherent series, and I do not care to dwell upon them longer than is necessary to point out that the literature of lead-poisoning and the history of one of these cases in particular, lends support to the view that purely nervous symptoms may be due to lead, and may exist for a long time without the supervention of signs of marked organic disease. Thus, Leudet, describing the cerebral symptoms which he had seen among a large number of painters, says:[6]

"Several painters, before they had shown any signs of cachexia, suffered from mental delusions, confusion and hebetude."

Insanity of different types has been reported by a number of writers.[7] Clevenger[8] has described a case of melancholic depression with epileptiform convulsions in a lead worker, associated with blue-line on the gums "and other symptoms of lead-poisoning," who recovered under potassic iodide and other treatment. Kiernan[9] besides giving a number of references to other writers, gives an analysis of thirty cases of insanity apparently due to lead-poisoning, which were observed by himself. Some of these cases confirm the opinion which I have expressed. I will refer to only one case of those which I have observed.

It is that of an intelligent Scotch workman in a factory-town of Massachusetts, who had used for ten years water which was drawn through a two-inch lead pipe, from a well twenty-five feet distant, the end of the pipe remaining in the well. His family history was moderately neuropathic. His symptoms consisted in tremor of the hands, which had first been observed three years before, after the confinement and debility attending an operation for hæmorrhoids. Ever since that time he has felt weak and has worked but little, partly from that cause, but mainly because of distressing nervous symptoms, such as noises in the head, a feeling of soreness at the vertex, and, especially, frequent attacks consisting in a sort of aura sweeping over the body and head, the so-called "rush of blood."

His appearance was that of an excitable, but intelligent and naturally healthy man. The pulse and heart were normal. There was no anæmia, though this may have been masked by a natural fulness of the cutaneous vessels. The lips and tongue trembled slightly, as well as the hands. Lead was found in the drinking-water and twice in the urine. At a third examination it was absent. His improvement under treatment was marked and continuous.

This case leads us naturally to the *next group*, where it perhaps more properly belongs. This group of cases is allied to the last, but characterized by a greater prominence of disturbance of the organic functions. The general complaints were rather of lack of vigor, and of special nervous symptoms, rather than of general nervous instability or erythism, and yet there was no sufficiently marked organic disease to demand a special pathological classification.

[6] Recherches sur les accidents causés par l'empoisonnement saturnine. Rouen, 1882.

[7] See Barteus; Allgem. Zeitschrift für Psychologie, 37, 1881, Ullrich; ditto, 1883.

[8] Chicago Medical Journal and Examiner, 1884; quoted in the Journal of Nervous and Mental Disease, April 1884, p. 308.

[9] Chicago Journal of Nervous and Mental Disease, 1881.

In this group there are nine cases, in all of which, as it happened, lead was found in the urine. Five of them were examined for lead simply because they showed muscular tremor of the hands, or hands and lips, associated with some general debility or vague pains. Two, were cases of "recurrent paræsthesia" of the extremities, a symptom which it has of late been suggested may be due to slight multiple neuritis. If that is true, it might be supposed that a certain proportion of the cases would follow poisoning by lead, which imminently tends to attack the peripheral nerves. One of the patients in whom these symptoms of debility and tremor were well marked, and accompanied with increasing nervousness and sleeplessness, of four years duration, was a printer, and his urine contained a large amount of lead. His knee-jerk was very lively, especially on one side, but this symptom was less marked at a second examination, and there was no ankle-clonus. Its possible significance will be referred to later.

This group is related to that which follows (fourth group), in which I have put together the cases where symptoms of multiple neuritis were present, with others in which symptoms of chronic myelitis were associated with those of neuritis, and finally a number of cases characterized clinically as "spastic paraplegia," and due, perhaps, to degeneration limited to the motor tracts of the spinal cord. I have also included two cases apparently of multiple sclerosis of the spinal cord.

In this group of cases the chief interest of this investigation centres. For if it can be shown that lead poisoning leads to the symptoms of spastic paraplegia, or to some forms of it, especially those which are somewhat irregular in their clinical history, and are associated with signs of peripheral neuritis, on the one hand, and with more or less disorder of the general nutrition of the body, on the other, we shall have made a practical gain in our knowledge of a distressing disease.

This group of peripheral, mixed paripheral and spinal, cases contains nineteen cases, in all but four of which lead was found in the urine.

Of the four in which no lead was found, one was a case with chronic progressive spastic and ataxic symptoms, attended with difficulty in the retention of urine. The patient was a young girl, and the case probably belongs with the developmental diseases of the spinal cord. The other three were pretty typical cases of spastic paraplegia, one of them associated with some muscular atrophy of the arms. The cases in which lead was found were characterized by such symptoms as the following:

(1) Paræsthesia of the hands and feet (two middle toes), twitching of the fingers, exaggeration of the knee-jerk, especially left.

(2) General feebleness; paræsthesia in legs with slight anæsthesia; twitching of muscles of legs; marked improvement under treatment; malarial history.

(3) Spastic paraplegia; cramps and twitching of the calves; knee-jerk and ankle-clonus exaggerated; history of chancre; lead found twice in urine and a considerable quantity also in drinking-water.

(4) Trembling of hands; sense of coldness and numbness in toes; lancinating pains in legs; fatigue on exertion.

(5) Marked progressive spastic paraplegia with myosis and loss of pupillary reactions; ataxia and some atrophy of hands.

(6) Progressive weakness and stiffness in legs with diffused and almost universal pains; marked tremor; great improvement for a time under treatment.

(7) Temporary pain in chest with slight dyspnœa; progressive numbness, heaviness and weakness in legs; eventually rather rapid recovery.

(8) Numbness in feet and legs with impairment of strength; tremor of hands and tongue; some wasting of small muscles of hands; temporary retention of urine.

One case is of peculiar interest as an instance, probably, of very severe and wide-spread neuritis of a type unusual in lead-poisoning, and characterized by a very marked ataxia; of motion, in short, a pseudo-ataxia of peripheral origin. It was reported briefly in the *Journal of Nervous and Mental Diseases*, January, 1887 (Case VIII.)

The next case is, I believe, of a similar though less serious character. It is that of a young lady [10] of fifteen, of excellent previous health, who during the six months previous to my examination, which was in April, 1887, had shown successively the following symptoms: diffused headache of moderate severity; numbness and prickling of right hand; temporary difficulty in completely controlling the sphincter of the bladder; some months later, strabismus coming on gradually and slowly increasing, attended by dizziness, confusion of eye-sight and eventually by double vision; at the same period, numbness and prickling of left hand, especially at the ends of the fingers, continuing day and night, but eventually passing away; moderate ataxia of both upper and lower extremities; grasp of the left-hand weaker than that of the right, and small muscles of hand perhaps slightly atrophied; exaggerated knee-jerk, and trace of ankle-clonus; impairment of motions of both eyes, especially right, almost or wholly confined to muscles supplied by third pair; steady and rapid improvement, apparently aided by potassic iodide; eventually complete recovery.

That these are instances of multiple neuritis, not as is the rule with lead-poisoning confined to the motor tracts, but involving the sensory as well, and thus causing the ataxia, cannot, I think, be doubted. Analogous if not exactly similar cases have been reported under the name of pseudo-tabes, due to peripheral neuritis from alcohol and arsenic [11] and Renaut, [12] in his excellent monograph on chronic lead-poisoning, reports one of the same kind, evidently due to lead, which was observed by Raymond, who says in another place, that he has seen three cases of the kind.

The next case is likewise interesting as showing symptoms of progessive spinal character, involving almost exclusively the motor functions and associated with marked anæmia. It resembled in these two respects another case which I have placed in a different group, characterized by progressive anæmia, progressive transverse myelitis and death.

The patient had been a carriage-painter for thirteen years. His present symptoms consisted in 'numbness" of the feet and legs throughout their full extent; fatigue in walking and marked muscular weakness, great constipation; similar symptoms in arms but to a less degree; no pain; marked exaggeration of knee-jerk and ankle-clonus. The duration of

[10] Seen in consultation with Dr. P. Wadsworth, of Malden, Mass.
[11] Gazette Medicale de Paris, 1876, Vol. 35.
[12] On Pseudo-tabes from Arsenical Poisoning, etc. Charles L. Dana. Brain, Part xxxvi, January, 1887.

the symptoms was about one year and a half. No albumen was found in the urine, nor other signs of chronic nephritis. The skin was very pale, with a yellowish cast. There is no distinct ataxia, and yet the movements are rather exaggerated; no history of colic; no apparent weakness of the extensors of the fingers; no blue-line. Lead was found twice in the urine. The patient improved markedly under iodide of potash and a large quantity of food, but lately has failed steadily. The exaggeration of the knee-jerk, and the presence of ankle-clonus, in this last and some of the preceding cases leads us to (group IV) the cases of spastic paraplegia, amyotrophic spastic paraplegia, and paraplegia with ataxia, to which I have already alluded. These, together with the cases of probable multiple spinal sclerosis, number ten, and in all but three of them lead was found in the urine.

(To be continued.)

CAN CIRRHOSIS FOLLOW TRAUMA? A CASE OF MEDICO-LEGAL INTEREST.[1]

BY DR. F. W. STUART, BOSTON.

THE case which I am to report is one of twofold interest, namely, from a medico-legal and from a pathological standpoint.

Oct. 3, 1885, during the service of Dr. E. O. Otis, J. B., aged ten years, came to the Carney Hospital. His family history was good. He had always been well up to 1882, when he had an abscess on the left side of his neck which suppurated for two years, and resulted in contraction of the left side of the neck. He had visited the Carney Hospital in June, 1885, when the following note was made: "Patient listless, loss of appetite, diarrhœa three days; contraction of sterno-mastoid on the left side due to an old abscess, tenderness over the site of the old gland and in the region of the pneumogastric." The patient complained only of swelling of his abdomen. He was very irritable, and cried so much that it was impossible to make a careful physical examination, though it was evident that there was fluid in the peritoneal cavity, fluctuation being well marked. He was given Syrup Ferri Iodidi, and told to return the next day for a careful examination.

The patient returned Monday, Oct. 5th, Drs. E. O. Otis, W. H. Devine and myself being present. We were now told that on the previous Tuesday the patient had been kicked by a schoolmate, and that the disease dated from the day of the assault. A careful history was now taken, and a thorough physical examination made. The patient's mother stated that he had always been well up to the time of the assault, with the exception of the abscess and the attack of indigestion mentioned before. She said that he was nervous and irritable, but attributed this to the fact that the boys of his age were constantly irritating him on account of his wry neck. Otherwise he was a strong, healthy and cheerful boy. On Tuesday, Sept. 29th, while playing in the street he became involved in a disturbance with a schoolmate, and, though an exact story of the quarrel could not be obtained, it was established that the patient had been knocked down and while lying on his back had been stamped upon, the heel of the assailant striking him in the abdomen. The patient spat up some blood, walked into his house not far away, complained of some pain, but the next day was able to attend school. On the Saturday following, his mother first noticed that his abdomen was swollen; and brought him to the hospital.

Physical examination showed the patient to be well developed for a boy ten years old, but he was decidedly pale and cachectic in appearance. His temperature was normal, and his pulse and respiration were but little hurried. Heart and lungs were normal. His abdomen was much enlarged and fluctuating. On percussion there was dulness everywhere, with some areas of flatness, and the percussion note was unaffected by a change in the patient's position. The urine was high colored, specific gravity 1021, albumen one-eighth per cent., and the sediment contained some renal epithelium, urates, and a few casts. The existence of an exudation was of course very evident, and a diagnosis of chronic peritonitis was easily made, but at the same time it was felt that there must be something underlying the peritonitis.

In attempting to diagnosticate the disease more accurately, some differences of opinion were developed, though it was considered to be very probable that the case was one of tubercular peritonitis. The absence of any tubercular trouble in any of his relatives, as well as the absence of any pulmonary signs in the patient tended to negative this view.

In a few days the distension became more marked, the genitals were very œdematous, and the breathing became embarrassed. On October 16th, the abdomen was aspirated, and about two quarts of a clear serous fluid were drawn off, it being impossible to aspirate more than a small part of the exudation, owing to its being sacculated. At the same time the genitals were punctured with a needle and the fluid allowed to trickle away. During this time the patient bled very frequently from his gums. Under symptomatic treatment the effusion largely disappeared, and the patient was able to attend school again. This improved condition lasted for some time, after which the fluid began to reaccumulate, and a scrotal hernia was developed on the left side.

Again there was improvement, and in May, 1886, the patient returned to the hospital to see if something could not be done for his neck.

Examination at that time showed still evidences of the exudation, and the borders of the liver and of the spleen were undeterminable.

July 3d, the boy who assaulted our patient was tried in the police court on the charge of having committed a felonious assault, and I was the only medical witness summoned.

The facts were testified to as stated above, though the testimony also unintentionally drew out the information that the patient had for months been subject to bleeding from his mouth.

I was asked whether in my opinion the kick received caused the patient's disease. I answered that I thought that the injury did not cause the existing trouble in the sense of starting it up, de novo, though I admitted that possibly it might have hastened a previously existing disease.

My conclusion was based on the following considerations. It did not seem to me that the injury had started up an acute peritonitis, because the patient was not very sick, that is, he had not been confined to his bed, he had no marked fever, and had not complained much of pain. Furthermore, it seemed to me that so

[1] Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, May 11th, 1887.

large an effusion thrown out in four days would have perceptibly embarrassed his respiration and quickened his pulse. Therefore it seemed to me that the assault merely served to call attention to a previously existing condition, which it at most had aggravated.

The question then asked was, Could the hernia be due to a weakening of the abdominal walls at the point of the injury induced by the kick? I thought not, and attributed the hernia to simple distension of the abdomen by the fluid.

Finally, I was asked if the spitting up of blood was not proof that the kick had caused some internal injury. I answered decidedly, no. The patient may have received a blow on the mouth, may have bitten his tongue in falling, and in any event this symptom could have but little weight in determining the force of a blow in one who so often before had "bleeding from his mouth."

The defendant was, however, bound over to the Superior Court, and a hearing before the grand jury resulted in the finding of a true bill.

July 25th, Dr. Devine was called to see the patient, and afterwards Dr. Otis saw the case with him. The patient then had great distension of the abdomen, and general œdema. Tapping was advised, but not consented too by the parents.

August 4th, the patient complained of great pain in his abdomen, his pulse was rapid, temperature high, and the general constitutional disturbance great. Dr. Devine, who was then attending the patient, attributed these symptoms to an acute exacerbation of the peritonitis. The patient died August 6th, and an autopsy was made by Dr. F. W. Draper, Medical Examiner, at 2.45 P. M. of the same day, Drs. Devine and myself being witnesses. Dr. Draper has very kindly sent me his notes of the case, which were as follows:

AUTOPSY.

By Dr. F. W. Draper, Medical Examiner, at 2.45 P. M., August 6, 1886.

Body very pale; a little livid discoloration of dependent parts.

Rigor mortis absent.

No appearances of decomposition.

General anasarca, — œdema of face, arms, hands, thorax, abdomen, genitals, legs and feet.

Abdomen distended with fluid; fluctuation well marked.

Scrotum large and red. At the left inguinal ring, there was an opening sufficiently large to admit the index finger easily.

Internal examination. The peritoneal cavity contained one hundred and seventy-two fluid ounces of clean, thin, serous fluid.

The heart was normal.

The lungs were œdematous and injected in their lower and posterior portions.

The spleen was enlarged to four times its normal volume; it was softened and its section presented limited areas of diffuse hœmorrhagic infiltration.

The kidneys were moderately enlarged, pale, with normal relations between the cortical and medullary portions; their capsules were free.

The liver was reduced to the size of a man's fist; it was of very dense consistency, light yellow color, with thick interstitial partitions between the lobules and a great number of small nodules upon its surface.

The intestines and apposing surfaces of the abdominal organs were firmly adherent at numerous points by strong bands representing a former inflammation of the peritoneum; and layers of soft lymph at various situations indicated more recent peritonitis. The peritoneum was thickened and opaque. There was no purulent exudation. The peritoneum and mesentery were œdematous and the dependent parts of the intestinal folds showed limited patches of hœmorrhagic infiltration.

The stomach and intestines presented nothing remarkable upon internal examination.

The mesenteric glands were normal.

The brain was soft and œdematous.

Diagnosis: Chronic interstitial hepatitis; chronic hyperplasia of the spleen; chronic adhesive peritonitis; ascites and general anasarca.

Cirrhosis of the liver is so rare a disease in childhood that many of the books specially devoted to children's diseases make no mention of it. Still, in a very hasty review of the literature on the subject, limited to the usual reference books, I find quite a number of recorded cases.

F. Weber[2] and Virchow[3] report congenital cases, Wettergreen[4] reports a case at four; Cayley[5] and West[6] each one at six; Loeschner[7] one at seven; Hauerwas[8] and Wilks[9] each one at eight; Murchison,[5] Frerichs[5] and Griffith,[5] each one at ten; Maggianni[10] one at eleven; Steffen[2] two cases, one eleven the other thirteen, and Wunderlich[3] observed two cases in sisters aged eleven and twelve years respectively. None of these are recent cases, since I did not have time to consult the recent journals.

It is generally admitted that the excessive use of alcohol is the usual cause of cirrhosis, but various others have been given. Flint mentions syphilis, chronic malarial poisoning, chronic phosphorus poisoning, chronic peritonitis, and occlusion of the bile duct as causes to which cirrhosis is often assigned, though he would doubt the efficiency of them. The excessive use of condiments and extension of a perihepatitis have also been charged with producing cirrhosis, while Griffith in the report of his case, alluded to chronic abscess as if it were a recognized cause of this disease. Of the cases cited, Wunderlich, Murchison and West (the latter's patient, a girl of eight being in the habit of drinking a half pint of gin daily) were able to prove that their patients had used alcohol to excess. Wettergreen and West attributed their cases to the excessive use of coffee. The writings of Virchow and the reports of the Italian physicians would lead one to believe that syphilis and chronic malarial poisoning may cause cirrhosis, but in the main one is almost forced to look upon this disease as a specific disease with its specific cause — alcohol. The reader has notes of a case of cirrhosis seen in Professor Bamberger's ward in Vienna. The patient, a girl eleven years old, gave a history of intermittent fever, and to this her disease was attributed. But long after she had been admitted to the hospital it was ascertained that her father kept a "Brantwein-Geschäft," thus making it, after all, more than probable that her trouble was due to alcohol, since in the family of such a man

[9] Quoted by Niemayer.

brandy was likely to be looked upon as a panacea for all our ills.

It must however be admitted that careful questioning fails to establish an alcoholic habit.

What caused the cirrhosis of the liver in our patient? Did the trauma cause it?

There was no history of the abuse of alcohol, there was no question of syphilis, since parents and brothers and sisters were all healthy and free from any signs of this disease, and the patient had never had intermittent fever. If the injury caused the disease, it first started up a chronic peritonitis, and secondarily to this came the cirrhosis. That such a thing is possible has been suggested, but I think it hardly probable, and in this case I feel that in June, 1885, when the patient was listless, etc., and a diagnosis of indigestion was made, he had beginning cirrhosis.

This would coincide with the opinion arrived at from his physical condition when I first saw him, that his disease dated back weeks at least.

According to Griffith, the chronic abscess may have caused it, but I failed to see the report of any case tending to support such a view.

In conclusion, let me say that I believe it wiser to admit our ignorance of the cause involved in a case so puzzling as this, than to refer it to so hypothetical a cause — as a chronic abscess.

RECENT PROGRESS IN OPHTHALMOLOGY.

BY MYLES STANDISH, M.D.

THE BACILLUS OF ACUTE CONJUNCTIVAL CATARRH.

WEEKS[1] has examined microscopically the mucopurulent discharge of acute catarrhal conjunctivitus. The first case that he examined was a woman of thirty years, in whom the disease had appeared three days previously. The ocular and palpebral conjunctivæ were greatly congested, the lids slightly swollen, and marked photophobia, profuse lacrymation, and a muco-purulent discharge were present. A cover-glass preparation of the secretion, stained with gentian violet, disclosed large numbers of small, well-defined bacilli which were aggragated on and in the pus cells, and free in the mucus. The case recovered in two weeks from the beginning of the attack, under the use of mild astringents. There were two children in the family, one of twenty months and one of four years. The first had suffered from conjunctivitis for two months, the second for six weeks. In both cases the palpebral conjunctiva was injected, and discharging muco-pus. The secretion from both these cases contained many bacilli, such as were found in the secretion from the mother's eyes. Both cases recovered in a week's time, under the use of a zinc collyrium. Dr. Weeks examined the secretions of all cases of conjunctivitis that came to the clinic for two months, without again finding the bacillus, when a man presented himself, who stated that his wife, three children and a servant girl, still had, or had recovered, from a similar form of conjunctivitis.

There was a muco-purulent discharge in each case. In two of the cases the attack was confined to one eye. The cases recovered, as the others had done, under a simple astringent treatment. In all of these cases the bacilli were found in large numbers. In order to determine the contagious nature of this conjunctivitis, Dr. Weeks inoculated the healthy conjunctivæ of rabbits with the secretion from one affected eye, but failed to produce any inflammation of the conjunctivæ. He then inoculated the healthy conjunctivæ of six eyes in five men, who had previously lost their vision, by transferring a small amount of the secretion from the patient's eye to the eyes that were being experimented on. In five of the six eyes inoculated, the same form of conjunctivitis was produced, the bacilli being found in the secretions. Attempts were made to cultivate the small bacillus on agar and gelatine, but although the conditions were made as favorable as possible, the bacillus did not develop. On particles of pus that were transferred to the tubes the bacillus developed rapidly, but could not be induced to feed on the agar, and disappeared in a few days. Subsequently a mixture containing only about 5 per cent. of agar was prepared, and upon this the bacillus developed rather feebly in tubes. It would not grow on plates. The bacillus in the tubes was contaminated with the club-shaped bacillus (or one which soon became clubbed), which developed as rapidly as the small bacillus, and repeated attempts to separate the two proved fruitless. It was easy enough to procure a pure culture of the clubbed bacillus, as it grows quite readily on 1-per cent. agar. Repeated attempts to cultivate the small bacillus on sterilized blood serum failed to carry it beyond the second generation. It develops rapidly in beef tea, but grows very feebly on potato.

The bacillus varies considerably in length, being from one to two micro-millimeters long; in thickness it is always the same, about 0.25 micro-millimeter. Compared with the tubercle bacillus it has about the same thickness, but is considerably shorter. The bacilli were sometimes joined together, forming quite long threads, the division between individual being very indistinctly marked. There was no tendency to a double arrangement, as in bacillus subtilis, or in Leber's bacillus of Xerosis of the conjunctiva. The bacillus under consideration stains readily with watery solutions of fuchsin, gentian-violet, and methylen blue, taking the stain a little less deeply than do the cocci and bacilli ordinarily met with. The eyes of both men and rabbits were inoculated with the pure cultivations of the clubbed bacillus, and no inflammatory reaction occurred. The healthy conjunctivæ of six children were inoculated with the result of the cultivation of the mixture of the small and club-shaped bacillus. The cultivations used for this purpose varied from the fourth to the eleventh generations. In all of these cases the typical muco-purulent conjunctivitis was produced, appearing in about forty-eight hours from the time of the inoculation. The bacillus was present in all as long as the yellowish discharge persisted.

THE MICRO-ORGANISM OF ACUTE TRACHOMA.

Michel[2] was commissioned by the royal government of Lower Franconia to investigate and determine more accurately the nature of an eye disease, seemingly the so-called "Egyptian Ophthalmia," which had broken out in the boys' orphan asylum at Aschaffenburg. The disease apparently was originally introduced into the asylum by a boy who had daily been in the city of Aschaffenburg, attending the gymnasium there. Of the inmates, there were not affected twenty-

[1] Archives of Ophthal., Vol. xv, No. 4.

[2] Archiv. of Ophth., Vol. xv., part 4.

eight, slightly affected fifty-five, and severely affected, fourteen. In the severe forms of the affection the picture of the so-called acute trachoma was well defined. The intensely swollen and hyperæmic fornix, the tarsal conjunctiva, and the conjunctivæ covering of the lacrymal caruncle, were studded throughout with extremely numerous follicles of translucent grayish red form the size of a millet-seed to that of a pea. On everting the lids the conjunctivæ folds sprang forward in a series of reddish ridges. The secretion was moderately copious and purulent, and ordinarily the vascular plexus of the scleral conjunctiva was deeply congested. In nearly all of the cases there was swelling of the pre-auricular glands. These glands were never painful, even on the strongest pressure. They were of moderately soft consistence and elastic. In about thirty or forty of these cases the secretions were examined for bacteria, and in no case could their presence be established.

Inoculations made upon agar-agar with the contents of a pressed-out follicle, developed, before the end of two days, a distinctly visible culture. In general, the cultures presented a thick coating, growing superficially, of a white color, inclining at first to gray, later to a trace of yellow, and with a moist glistening surface and sharply limited borders. The cultures which developed most quickly were those made by inoculation of blood serum and agar-agar at the temperature of the body. In nutrient gelatine the culture developed more slowly, and likewise in egg-albumen. On potato the growth was very feeble. Morphologically, the cultures consisted of diplococci. The double cocci, appearing as if two segments of a ball, resemble the gonococci, and evince an inclination towards grouping themselves in masses similar to sarcine. They are, however, much smaller than the gonococci. Specimens of cocci measured, by means of a Zeiss objective (homogeneous immersion, $\frac{1}{12}$), and of an eye-piece micrometer, gave as average results the following measurements: Length from pole to pole 0.6-08 μ., width in centre 0.4-0.6 μ. The trachoma coccus is distinguishable from the gonococcus, furthermore, by the greater thinness of the line of separation, which in general only becomes distinctly visible under strong magnifying power. It shares with other fission fungi the power of absorbing dye-stuffs, and displays a great affinity for the basic aniline colors. The conjunctivæ of rabbits were inoculated by pricking, and the introduction of bits of the follicle and also of pure cultivations. The results were entirely negative. Knowing that the conjunctivæ of rabbits seems to possess considerable immunity against micro-organisms, as for instance, the gonococcus, Michel regarded it as justifiable to make such inoculations in a certain case upon a man. In this case the right eye had been enucleated, and the left was, owing to meningeal atrophy of the optic nerve, almost entirely blind. Numerous fine superficial pricks were made in the conjunctivæ folds of the upper and lower lids of the right, with a small needle which had been immersed in blood-serum culture. After forty-eight hours an increased mucous secretion was observed, and a few small follicle-like elevations were noticed, which two days later were seen to have increased in size. In the further course of the case fresh elevations appeared in the neighborhood of the altered places, so as to give a complete clinical picture of follicular disease of the conjunctivæ fold. Ten days after the inoculation a follicle was excised, the contents pressed out, and the same inoculated in blood serum. The characteristic culture developed and was recognized by the microscope as a pure culture. Upon the microscopic examination of portions of the affected conjunctivæ, the cocci were never observed in the epithelial layer, but only in the tissue of the follicle itself. They are generally in the form of irregular, roundish heaps, and appear to lie on or between the cells rather than in them.

INCISION OF THE SWOLLEN OPTIC NERVE-SHEATH.

Carter [2] advocates the incision of the swollen optic nerve-sheath behind the eyeball in certain cases of choked disc, and reports the case of a woman with monocular optic neuritis and blindness of the temporal half of the visual field. Headache had existed for ten days, and the left optic disc was much swollen. Mr. Carter considered the swelling due to a descent of fluid from the subarachnoid space to the space between the dural and pal sheaths of the optic nerve; the nerve was compressed by the fluid and the venous circulation was impeded. Under iodides and mercury no improvement resulted. The disc swelled still more; hæmorrhages and patches of exudation also appeared; and with the assent of Dr. Hughlings Jackson, Mr. Carter decided upon an operation, which he first practised on the dead subject. The external rectus muscle was divided; the eyeball then rotated inwards; the sheath of the optic nerve was exposed and opened, and gave exit to the contained fluid. Recovery was uninterrupted, the patient was at once relieved of the headache, which did not return for a month, and ten days after the operation the swelling of the optic disc was found to have diminished one half. Further recovery has resulted.

(To be continued.)

Clinical Memorandum.

IS TUBERCULOSIS OF THE LUNGS EVER CONTAGIOUS? [1]

BY F. I. KNIGHT, M.D., BOSTON.

In July, 1885, a young lady of 19, came to my office with a history of cough of nine months duration. I found signs of phthisis in one lung. Her father was a very strong man; her mother had died of some nervous trouble after child-birth. There had been ten children, five of whom died in infancy, none of them with any brain or lung disease. There had been also six half-brothers and sisters, one of whom had died in infancy. Of the uncles and aunts on both sides, only one uncle had died of phthisis. The patient gradually declined, and died April 15, 1887. She was accompanied in her visits to my office by an older sister, twenty-three years of age, who had given up everything to attend to her. This sister, while not robust-looking appeared well, and said that she had always been so. She occupied the same room and bed with her sister. This I protested against, and advised her to go out regularly every day for walks in the fresh air.

The last record made of their visits to me was in the latter part of October, when the phthisical patient became too sick to come to me, and went under the

[1] Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, May 12, 1887.

[2] Lancet, March, 1887, p. 626.

care of her family physician in a neighboring city; she died, as I said, on the 15th of April. On the 19th of April the sister came into my office with the following history. She had continued to attend closely upon the invalid all winter, and had disregarded all my advice. She had even slept with her sister up to within five weeks of her death. She was with her night and day. During the latter part of her sister's life her breath was so offensive that she could eat almost nothing, and only kept herself up by the free use of stimulants. She stated that she had had a little dry, hacking cough for a month. She breathed rapidly, but said there was no dyspnœa. On examination her pulse was found to be 140. Temperature, 104°. On examination of the chest, subcrepitant râles were heard in both upper lobes, front and back, and the diagnosis of acute pulmonary tuberculosis was made. Examinations, April 26th and May 3d confirmed the diagnosis. On the 21st of May, she came to my office so weak that she had to be assisted from the carriage to the house. She reported hæmoptysis of several ounces two weeks before. She was so weak that I did not examine her chest. Pulse, 160; temperature, 103.4°. I did not see her again, and she died June 17, 1886, about two months after I first examined her, and three months after the beginning of the dry cough.

Who can fail to believe that the disease and death of this patient was caused by attendance upon her sister? Hardly any one will deny this. Admitting it, would she have succumbed to acute *pulmonary tuberculosis*, if she had attended upon a sister ill with some other disease? As she had no such hereditary tendency I do not think so. How often do we see patients worn out with much longer attendance upon the sick, and yet not become tuberculous! And how often do we see strong women without the slightest hereditary tendency succumb to attendance upon tuberculous patients.

It is useless to allege in this connection, that ordinary attendance upon the sick in consumptive hospitals does not affect the attendants. I admit this fact, but the attendance is not so prolonged, nor so close as in families. Let any one who has doubt about the clinical evidence bearing upon this point read the little brochure of Webb. The fact is that tuberculosis is so common with us, that we have almost ceased looking for the immediate cause in any case, especially if relationship gives us a chance to attach the blame to heredity. I believe, however, that there are hundreds who have by inheritance that peculiarity of pulmonary soil which favors the development of the tubercular disease, who would not show it unless they were brought into contact with those already affected. Whether all cases require such a transmission of germ we do not know.

In what manner is it probable that the disease is communicated? It has been claimed that bacilli have been found in the breath, but it is, perhaps, more probable that the communication in most cases is by dried sputum, which becomes diffused in the atmosphere. We have abundant proof that tuberculosis can be readily communicated to animals little liable to it, for example dogs, by causing them to inhale for an hour or two a day an atomized solution of the sputa of tuberculous patients. (See the experiments of Tappeiner and others in substantiation of this statement).

So then, I say that the appearance of tuberculosis of the lungs in countries where it was previously unknown, with the ingress of people from countries where it was common, the marked increase in the disease in the neighborhood of health-stations resorted to by the tuberculous, the personal history of the development of cases in our midst, and experimental work with the sputa, all point strongly to the probable communication of the disease under favorable conditions, and make it not only incumbent upon us, in case of pulmonary tuberculosis in a family, to establish precautions against communication of the disease, but makes us criminally negligent in failing to do so.

What precautions shall we take? These pertain (1) to the patient; (2) to the quarters he occupies; and (3) to the exposed attendant.

The patient should be made careful in the disposal of his sputa, either to deposit them in a cup in which some germicide has been placed, or if the patient is feeble and obliged to use cloths let them be destroyed before any drying occurs. It would hardly seem to be necessary to warn respectable patients not to spit about them carelessly, yet I have seen with respectable people the most utter indifference in this regard. I have seen a patient with hæmoptysis lying in bed on his back letting fly his expectoration in every direction, so that the bedding, floor, and walls of the room were well covered with sputa. I have seen a beautiful prima donna of the opera spit right and left over a handsome hotel carpet. Neither of these patients was American. I have, however, seen an American, a distinguished citizen, afterwards United States Minister to one of the European Courts, sit in the office of a distinguished consultant, and squirt a sickly stream of tobacco-juice between his teeth, over a fine straw carpeting just laid.

For disinfection of the spit-cups, Dr. Ernst informs me that a five per cent. solution of carbolic acid is the best. Corrosive sublimate does not answer, as it coagulates mucin, and does not reach the bacilli at all.

In regard to the room: we should secure change of air by every known device, and as long as possible by a daily removal of the patient from his room, for the purpose of thorough ventilation. Clothing and bed-linen should be frequently changed. The absolute value of antiseptic sprays for the room in such cases we know not, and the use of those which are offensive in themselves should not be recommended. But such as are pleasant to the patient and attendant would be of service at least in counteracting the disagreeable odor which attends the last stages of pulmonary disease.

In regard to the exposed persons, let it be said that from the moment tubercular disease is discovered, another person should not occupy the same bed, not only for the sake of the exposed person, but also that of the patient, who will rest much more comfortably alone. Sleeping in the same room should also be forbidden, as we seem to be more susceptible to all infectious diseases during sleep. The attendant should have daily exercise in the open air, and if a relative, an occasional complete change, if possible. In case of any failure in health, this should be insisted upon, and although the physician cannot always prevent self-sacrifice on the part of friends, he can often modify it. At any rate, he should not feel that relief of his patient was his only duty, but that his duty extended to the surroundings of his patient, and required that

these should be arranged with due regard to the protection of relatives and friends.

If there is any decided hereditary tendency to the disease, relatives should, if possible, be prevented from any attendance upon the sick, and put at once upon proper hygiene.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

MAY 11, 1887. The meeting was called to order at 8 o'clock, by DR. F. I. KNIGHT, Chairman. On motion, the records of the last meeting were omitted.

The first paper was by DR. F. W. STUART, entitled

CAN CIRRHOSIS FOLLOW TRAUMA? A MEDICO-LEGAL QUESTION.[1]

Dr. Stuart stated that the medico-legal character of the case, the important questions involved in the examination of the subject had made it a most interesting experience to him, and had taught him some very valuable lessons. It had served to somewhat change his views of the character of the legal investigation of such a case, and had diminished his respect for some of the methods employed for that purpose.

Dr. Stuart said: When I was called into court on this case I was summoned by the prosecution, the evident intention of the District-Attorney being to have as little medical testimony as possible, and to get hold of the youngest physician and break down his testimony. The defendants then tried it. They brought up witness after witness, and finally the policeman on the beat, all of whom testified that this boy was strong and healthy; except one boy who admitted that they called him "pot-belly" once in a while, on account of his protuberant abdomen.

During the trial I was asked to give an exact diagnosis. I said I could not. The judge said that "it made him tired" to hear a doctor say that this boy had been sick when so many people who knew him intimately and saw him daily, testified to the contrary.

After this trial I came to the conclusion that if a young man goes into court and is not sure of his case, he will be brow-beaten and all efforts made to confuse him. I think that this is one of the most difficult places a man can occupy when he is forced to admit that he cannot make a diagnosis. We did not make a diagnosis. This case was one that certainly has given me a great deal of confidence, from the existing medical knowledge of to-day, that that boy had cirrhosis of the liver. I was then inclined to believe, and am still confident that the injury did not cause the trouble which we did not diagnosticate.

DR. BLODGETT said that the insidious character of the disease in the present case, its great gravity, and its fatal termination forcibly reminded him of a case seen at a distance from Boston, in which a somewhat similar and equally unusual course of phenomena were noticed. The patient was a literary gentleman, well known to many members of this Society, who while in the enjoyment of his ordinary good health, was surprised to find that he was becoming weak, and particularly that he was troubled by shortness of breath on making any exertion, sometimes experiencing almost the condition of asphyxia. After a time he sought medical advice, but was able to give absolutely no satisfactory history of the character of his disease. Physical examination revealed the fact that the left side of the thorax was the seat of an extensive pleuritic effusion, the liquid reaching to the level of the sixth rib in the nipple line. Twenty-four hours later, the fluid had increased to such a degree, that there was constant oppression in breathing, and the level had risen to the fifth rib in the axillary line. The case was diagnosticated according to the rational and physical signs, as acute pleurisy, but was considered peculiar from the entire absence of any of the ordinary symptoms of this disease. The case passed into the hands of a very distinguished practitioner, who treated the patient by the constant exhibition of alkalies, and frequent and abundant catharsis, without, however, any attempt to relieve the distension of the pleura by aspiration or puncture, and the patient rapidly sank, and died at the end of four days.

The autopsy showed the conditions diagnosticated during life to have been correct.

DR. HAROLD WILLIAMS asked if the autopsy of Dr. Stuart's case showed any signs of the chronic abscess from which the boy had suffered some years before?

DR. STUART said that there was no internal evidence of any lesion referable to the abscess, no trace of which was found. Griffiths, however, mentions this as one of the causes of cirrhotic disease of the liver.

DR. WILLIAMS remarked that in answer to the question "was the injury the cause of the cirrhosis?" it was conceivable to suppose that the kick might have been the cause of the chronic peritonitis and that the adhesions resulting therefrom might have acted as a cause of the cirrhosis by constricting the blood-vessels of the liver. Dr. Williams asked if the adhesions noticed in this case were found to cause such interference.

DR. STUART replied that this was not the case: That it had been discussed at the autopsy, but that while many adhesions were found, none were in such position as to warrant such a conclusion.

DR. F. I. KNIGHT then read a paper on

THE CONTAGIOUSNESS OF TUBERCULAR DISEASE OF THE LUNGS, WITH A REPORT OF ONE CASE.[2]

DR. STUART: Mr. President, When I was at the Carney Hospital I saw a case of a young lady; she was the stepdaughter of a consumptive who had just died; the question as to whether her mother died of phthisis could not be brought out. The patient did not seem to know. She was one of a family of eight brothers and sisters, all well, and she alone had evidence of phthisis. According to this patient's statement, while her step-mother was sick for fourteen months she had hardly been out of the house. Dr. Devine, in speaking of the case, said he knew of a draw-tender who had buried two wives of phthisis; the draw-tender had the disease of course, himself, and the only conclusion which he could draw from this case was that the draw-tender was out in the open air almost all the time, while his successive wives

[1] See page 76 of this number of the Journal.

[2] See page 79 of this number of the Journal.

were shut up in the house, and thus the course of the disease was made quicker for them.

DR. BLODGETT said that he could not refrain from calling attention to a fact in relation to tuberculosis, which is not sufficiently considered in the treatment of cases of this disease. He was happy to observe that the chairman had laid stress upon the same point, namely, the eminently infectious nature of tubercular disease. There is no doubt that many cases of tuberculosis are communicated from one person to another, but the cases are not followed with that care which is everywhere thought desirable, even imperative, in relation to other infectious and contagious diseases. The time has probably not yet arrived when we can test this class of diseases in the manner which would be applicable to other communicable diseases. We are too much under the domain of public opinion to venture the rational and only real method of treatment which is directed to the peculiar character of the malady in question. We cannot properly utilize the knowledge which we already possess in relation to tuberculosis.

In some foreign hospitals, patients with tuberculosis are treated in the same manner as are those with other dangerous disorders; that is, the sufferer from tuberculosis is segregated from other patients, and is isolated in a ward devoted to infectious diseases, where he is subjected to a rigid seclusion from the other sick to whom the disease might be communicated. Much the same care and seclusion is exercised in relation to tuberculosis as is done with scarlet fever, measles, etc. Dr. Blodgett said that he had recently had a case under his own care in which the germicide treatment was adopted as one of the principal measures of relief, and in which there was an entire disappearance of all symptoms of disease. The patient is the son of a clergyman, and is about forty years old. His father was for many years a sufferer from chronic pulmonary disease, and died after attacks of pulmonary hæmorrhage, presumably of tuberculosis. The mother is still living, but has long been in feeble health. The patient was never a strong man, but maintained his ordinary standard of health until five years ago, when he was the subject of fistula of the anus, for which he was under treatment by surgical measures for a year. Since that time he has been somewhat feeble, and eighteen months ago he began to fail perceptibly. Twelve months ago, he was under treatment for hoarseness, which advanced to a degree which rendered speaking above a whisper almost impossible. At this time he came under the care of Dr. Blodgett, who found distinct ulceration of the larynx, with induration and impaired mobility of the vocal structures; and by microscopic examination the bacillus of tuberculosis was readily demonstrable. The patient was at once placed under treatment by means of tonics, removal to the country, the use of antiseptic lotions and inhalations, principally of mercuric bichloride, the employment of which was rendered tolerable by means of antecedent applications of cocaine. He passed some months on the sunny side of a hill selected with some care in New Hampshire, and late in the autumn returned to Boston. He gave up his previous residence, and removed to the highest part of Newton, into a new house, on sandy and dry soil, where he has since resided. He has steadily improved, his weight has increased from 122 pounds to 140 pounds. He has never been so heavy as at present. He is gaining strength, the voice has returned, and there is every reason for believing that the disease has entirely disappeared.

It is true that this was probably not a case of *contagion*, but it is illustrative of the way in which a disease which is contagious should be looked upon. It would, in all probability, have been perfectly possible for this patient's wife or child to have acquired the disease, by contagion. He had constant attacks of bronchial or pulmonary irritability, frequent catarrhs, and recurrent periods of hoarseness and threatened pulmonary tuberculosis. His system furnished a soil which was peculiarly adapted for the reception of such a disease.

DR. HAROLD WILLIAMS remarked that when a student he had been taught by Dr. Knight that phthisis pulmonalis was communicated by the sick to those in attendance upon them under certain conditions, and that in his practice he had never had occasion to change this view. He had not come prepared to cite cases in proof of this doctrine, but could say that he had never doubted its truth, and that he had each year many cases which confirmed it both at the Boston Dispensary and elsewhere.

The two principal arguments against the view of contagion were: *first*, that phthisis was the commonest disease in our community, one-fifth of our people dying of it, and that cases of its supposed contagion were cases of coincidence. This argument Dr. Williams thought could be answered by saying that the reason of its frequency was because of its contagiousness, and the absence of sufficient precaution in protecting the well against the sick. The second argument of the immunity of the attendants of phthisical patients in hospitals had been answered by Dr. Knight.

Dr. Williams not only believed phthisis to be contagious, but he believed the bacillus to be the element of contagion, and this had suggested to him that the well-known germicide properties of arsenic might account for the efficacy of this drug in phthisis, and that he was conducting some experiments to test this theory. Since reading Jaccoud's book, in which the administration of arsenic is highly recommended, Dr. Williams had employed it in several cases with good results, especially in one girl with phthisis of three month's standing, in which case its administration had been followed by complete recovery. Dr. Williams questioned if the good effects so strongly insisted upon by Jaccoud might not be due to the germicide properties of the drug, rather than to its action as a tonic, and as diminishing blood pressure and calming nervous irritability, as claimed by Jaccoud.

DR. HENRY J. BARNES addressed the Section upon the subject of

MILK-SUPPLY,

as follows:

"At the meeting of March 9th, a preamble and resolution relating to the milk-supply was laid on the table. I move that it be taken up and read.

"Mr. Chairman, the subject of milk-supply has been before us for several years, so that I feel we are all sufficiently informed to now take intelligent action on this resolution. Thus far our influence has been exercised in promoting legislation, and in support of the vigorous policy of our local and State inspectors. Valuable results have been accomplished, highly creditable to these officers, but the last

annual report of Professor Babcock, indicated a persistency in wrong on the part of a few dishonest milkmen, hardly paralleled in the annals of crime. During the past year 167 complaints have been made against 88 different milk-men for having in their possession dishonest milk.

"I think I speak within bounds in stigmatizing this crime, for it not only cheats the purchaser but assails the lives of many innocent beings.

"Professor Babcock publishes the names of those complained of during the past year, and in the list Bennet & Beckman appear twice; Charles M. Black appears four times; Henry S. Draper, five; Byron Eames, four; Seth Eames, four; Stephen F. Forbush, four; Albert F. Hale, five; Benj. F. Holt, fifteen; Chas. E. Kendall, four; Chas. A. Kenneson, six; John H. Kenneson, five; Mary P. Merriam, seven; Joseph W. Moore, seven; Orson Young, five; besides many others which appear once, twice or three times each.

"This dark record I believe to be chiefly due to a faulty system, which holds for twenty-four hours in secluded and often unsanitary places, milk which should go directly from the car to the consumer, as is the custom in other cities, so far as I am informed. As a rule only those persons who take milk by wholesale receive their supply on the morning of its arrival in Boston. I cannot believe there is any person here but desires a reform in this regard, although we may differ in opinion as to the best method of its accomplishment. Two or three months ago I presented this phase of the question to the Farmers' Club, and several gentlemen present advocated additional legislation to meet the case, but it was finally concluded that efforts to amend the present law might result in weakening the statute. Besides, it is extremely distasteful to medical men at least, to go before a committee and there be met by those who would attempt to impeach efforts for the public welfare by questioning disinterested motives. Therefore, this plan does not seem to be advisable.

"The other alternative is to create a public demand for a direct supply, and this is the object of the resolution, although it purposely limits action on the part of members of this Society to the exercise of such influence as they may see fit, leaving to each and all absolute freedom in selecting their source of supply.

"The coöperation of all honest dealers may be anticipated in this movement, as it will obviate the necessity of keeping in stock a large number of small cans, with the attendant care, and the maintenance of ice-chests which adds materially to the cost of handling. It would render inspection less laborious, as the samples could be taken from comparatively large quantities."

Dr. Barnes then offered the following resolution:

Whereas, A large proportion of the milk daily supplied to the City of Boston for human consumption by its inhabitants is from six hours to twenty-four hours old when it reaches the city, and

Whereas, Owing to the inconvenient time of arrival of the milk-trains, and to the system of delivery in small service-cans, the milk so brought is still further detained twenty-four hours in the barns and sheds of the milkmen, and

Whereas, We are of the opinion that during this period, not only are opportunities afforded to the dishonest dealer to tamper with the milk, but that it is often exposed to unsanitary influences, the cost of handling is increased, and the additional age thus given to it is detrimental to the public health, therefore,

Resolved, That we, the members of the Suffolk District Medical Society, Section for Clinical Medicine, Pathology and Hygiene, will exercise every proper influence to secure for ourselves and the community in which we live, milk which has not been subjected to this unnecessary delay.

Voted, That the Secretary of this meeting be instructed to endeavor to secure the publication of the above resolution in the daily papers of the City of Boston, over the signature of the Chairman of this meeting, and that of the Secretary.

The Chairman then declared the resolution to be before the Section, and invited Prof. James M. Babcock, the Inspector of Milk, to open the discussion.

Professor Babcock spoke as follows: Mr. President: I had no idea when I was invited by Dr. Barnes to come here that I should be called upon to speak, and I feel all the more diffident, now that I have observed that such matters have been brought before the Society in the form of papers prepared with a considerable degree of study and care. It will be evident from what few remarks I make that I have come here with no preparation whatever. I shall of course be glad to answer any questions in regard to this matter, that any gentleman may see fit to put to me.

It is as Dr. Barnes has said: a very large part of the milk which is supplied to the citizens of Boston is twenty-four hours in the hands of the milkman between the time when it arrives in Boston and the time the milk is supplied to the consumer, and is in many cases thirty-six hours old from the time of milking. On the Boston & Albany Railroad there is a train, of some six or seven cars, which gets in the city at half-past one, A.M., there are also some two or three cars which arrive at about eleven o'clock. On the other roads, the Boston & Maine, Eastern, Lowell and Fitchburg, etc., the milk is received at about ten or eleven o'clock in the day; of course the milk under that arrangement of trains cannot be delivered to the citizens of Boston till the next morning. The remedy for that would be a different arrangement of trains. The milk which is received by way of the Boston & Albany, is loaded directly on the teams in large cans and taken to grocery stores and bake shops, while the family trade is supplied by milk which was put up the day before. The milkman, after he has gone his rounds, perhaps visits the depot for the milk which has arrived on the eleven o'clock train that day, and takes it to his own stable and puts it up in small cans and then puts them into an ice-house or ice-pit and then at twelve o'clock or one o'clock in the morning, his wagon starts on its rounds to deliver this milk to his customers, so-called "fresh from the cow." There would be probably a certain amount of disinclination to enter into any arrangement which would make it possible to deliver milk in a fresher condition than it is at present. I ought to say, perhaps, there is a good deal of milk brought into Boston from Lexington and other outlying towns where the milkmen make their own contracts with the farmers, and the milk which is put up in the evening, is delivered to his customers the next morning. The proportion, however, is not perhaps over ten or fifteen per cent. of the milk sold in Boston.

Of course the less handling milk has, the better.

It does not seem so me that the pouring from a large can into a small one and then setting aside, is objectionable.

Of course the increased age of the milk is very objectionable: but anything which will prevent the taking of this milk into stables, some of which are certainly not in a condition to warrant investigation, will doubtless work an improvement in the quality of the milk. Something should be done to enable us in our department to visit these stables. There are in Charlestown many such stables, and the inspectors should be granted the right to enter all places where milk is stored or kept for sale in order to ascertain the manner in which these stables are kept.

DR. DURGIN was called on by the Chair, and responded as follows: I do not know that I am prepared to say anything on this subject, but I wish to call the attention of my friends here to the fact that very much can be done in the way of delivering milk earlier than it is now delivered. I am aware of the fact that much of the milk delivered in Boston is at least twenty-four hours older than it should be.

Everybody knows that the older the milk, the worse it is for use. I think that the profession is well aware of the fact that the mischief created in children during the summer season is by milk that is tampered with by means of water which is not of the best. The cream is also taken from it and water is added, which prevents the child from obtaining a proper nutrition from that which is taken. As far as resolutions are concerned, it seems to me that the profession is the one to start a movement of this kind. Certainly there is a call for such action on the part of the medical profession, and it seems to me that this is the place to do it. As far as legislation is concerned, there has been a very strong effort made at the State House to break down the existing law, which is a fairly good one. Thus far the attempt to make any inroad on the law has not been successful. In regard to the condition of the stables, I do not know that there is any law which would empower the Board of Health to enter these buildings, which are private property. The only way in which it occurs to me that we might reach them, is through a general law which would enable the Board of Health to investigate such places on the ground that they constitute a nuisance, and are a source of danger to the public health.

There is no doubt that the public has great need of instruction in regard to matters connected with its milk-supply, and these resolutions which have been proposed may have a very excellent effect in educating the public in some of these things which they ought to know. I have had occasion to say elsewhere that probably three-fourths of the people of the City of Boston firmly believe that whatever may be true of other people's milkmen, in the way of fraud and deception, *their* milkman is honest and truthful, and that somewhere in the radius of ten or fifteen miles of the city he keeps cows, and milks them and brings the products of his dairy to their doors. There are very few people who know the manner in which the milk business is carried on. The great majority of the milk-consumers of Boston suppose that the froth which they find on the top of their cans in the morning is the same kind of froth which they may have seen on the top of the milk while being drawn from the cow, in some cool farmyard in the country. They know that the froth rises to a considerable degree above the milk, and they are pleased to see the same appearance on the top of the milk can. They do not know that this froth is manufactured from a mixture of the white of egg, and a little cream, and is carefully placed on the top of the milk after it is put in the can. This compound is called by the milkmen "spudge," or in the more common vernacular of the milk trade, it goes by the name of "flub dub."

The public is to a certain extent to be blamed in regard to the quality of the milk. The milkmen justly complain that in certain sections of the city the people are not willing to pay what good milk is worth. I am obliged to confess that I have a feeling of suppressed sympathy for certain milkmen; I would like to believe that it is the force of circumstances which compels some of them to water their milk, and take the cream off, in order to get a living. There are certain sections of the city where the people are unwilling to pay five cents a quart for good milk, to have the milk brought to them.

DR. B. F. DAVENPORT said: I have had within a week or ten days an illustration of the degree of interest and information which the average milk-dealer has in the production or care of milk. I recently saw a milk dealer who had just arrived from Chicago. On the journey to Boston he rose early one morning, and looking out of the window of the sleeping-car, he saw a farmer milking his cow. The milk-dealer stated that it was the first time that he had ever seen a cow milked in his life.

The system of milk-supply in Boston is different from that of any other large city in the country. There is no other city which is supplied exactly like ours. The larger part of the supply is brought in by railroads and is put up for family use in large cans. In New York it is carried around in large cans and is ladled out into pitchers, etc., as it is desired by the consumers.

In other cities, Philadelphia, Baltimore, Chicago, they have very little railroad milk, but the supply is mostly from dairies in the suburbs of the city. There is another point in which the consumers are at fault for the quality of the milk. As the milk is supplied the cream has risen to the top of the can, and ordinarily the consumer will pour off the top of the can without mixing, and the lower portion then acquires a bluish appearance. The consumer thinks that this is not as it should be, and at once concludes that the milkman is not delivering honest milk. He thinks that the milk should be of the same appearance at the bottom of the can as at the top. I have known a case in which a pedler said that he was compelled to adulterate the milk in such a way as to make the bottom of the can appear as white as the top, in order to sell the milk.

DR. BARNES stated that he had been repeatedly told by the contractor on the Boston and Albany road that he would much prefer to have the whole supply of milk come into Boston so as to be delivered in the morning.

The Chairman then put the resolution, and it was unanimously carried. The Secretary was directed to secure the publication of the preamble and resolution in the daily papers.

The Section adjourned at ten o'clock.

— One hundred and sixty-five people died in Chicago, July 15, 16, and 17, from the effects of heat.

THE NEW YORK ACADEMY OF MEDICINE.

Stated meeting, June 2, 1887.

INTUBATION OF THE LARYNX.

Dr. F. Hubel read a paper based on a study of forty-seven cases, the results of which had convinced him, he said, that at the present time tracheotomy should only be resorted to in cases in which intubation had failed to afford the needed relief; and he was of the opinion that a case of this kind would seldom be met with. Having stated that the dyspnœa was as effectively relieved by intubation as by tracheotomy, he spoke of the advantages of the former, and also referred to the origin of the procedure as proposed and practised by Bouchut, in 1858. Then, after referring to some practical points derived from his personal experience, he said that intubation had now passed through the experimental stage, and that its utility had been fully established by numerous operators in different parts of the country. Notwithstanding the gratifying results obtained, however, it had as yet received very little favor, or even attention in Europe.

Of his forty-seven cases, Dr. Huber said that twenty-nine, with eleven recoveries, were in children under three years of age, and eighteen cases, with nine recoveries, in children of three years or over. Of the children under three years, one was nine and one-half months old, one, ten and one-half months, two, eleven months, one, one year, two, two years, two, two and one-half years, and two, two years and eight months old. Of all the children that he had been called upon to treat who were suffering from laryngeal stenosis he had found it necessary to resort to intubation in only one out of every three or four cases; and he thought that it should not be practised until dangerous symptoms had supervened. He used it, in fact, in exactly the same class of cases in which one year ago, he would have performed tracheotomy. Having spoken of the diagnosis of croup and the indications for surgical interference, he referred to the importance of making a careful examination of the neck and chest, and said that he had known cases of retro-pharyngeal abscess and empyema to be mistaken for laryngeal stenosis. As confirmatory of the diagnosis of the latter, relative absence of fever, in uncomplicated cases, was of much value; and aphonia, with difficulty of both inspiration and expiration, were positively indicative of croup.

He next spoke of the various accidents and mishaps which had been met with in connection with intubation, and the objections raised against the procedure. He referred first to the gag, and said that O'Dwyer's gag was liable to be displaced by the struggles of the patient, but that this was not the case with the one devised by Dr. Denhart, which he exhibited. The thread attached to the tube should be eighteen or twenty inches in length, and if not withdrawn at once, should be passed over the ear and secured. In order to avoid accidents in introducing the tube the efforts to place it in position should be short and repeated, rather than kept up uninterruptedly for any length of time. One of the most serious accidents that could occur, was the pushing of dislodged membranes before the tube, and in a case of this kind, Dr. E. D. Fergusen, of Troy, was obliged to resort to tracheotomy.

Several deaths had been reported from this accident, and Dr. Waxham had recently devised a long tracheal forceps for the purpose of removing the membranes when it occurred. In a case of his own in which it happened he gave the child brandy, with the effect of exciting a fit of coughing which expelled both the tube and the membranes. If at any time after the tube had been introduced, noisy breathing should set in, it was an indication for the temporary removal of the tube. The tube had been known to be coughed up and then swallowed. Instances had also been reported in which the tube had slipped through the larynx into the trachea; but this was when the earlier pattern of tube, with small head, was employed. The tube did not act as a foreign body when in the larynx, giving rise to choking sensations and coughing; but if it remained in position for a considerable length of time it might possibly produce slight ulceration. This, however, did no harm.

In speaking of accidents in connection with the withdrawal of the tube, he said that instances had been reported in which it was pushed down into the trachea, but this had occurred only when the older pattern of tube, with small head, was employed. As to the time for removing the tube, in some cases this might be done as early as the fourth or fifth day, although it was often desirable to allow it to remain longer. As a rule, however, it could be dispensed with at a much earlier date than the tracheotomy tube. If the respiration continued free, the tube should generally be allowed to remain until the fifth or sixth day; but if the respiration became noisy, it should be promptly removed, and afterwards re-introduced, if this should prove necessary. When there were diphtheritic patches discernible in the nose or pharynx it was advisable, as a rule, to leave the tube in position until they had disappeared.

In intubation, as in tracheotomy, the prognosis was more favorable when there was simply local obstruction in the larynx than in cases where there was marked constitutional infection from the diphtheritic poison. No age offered a contra-indication to intubation. No positive prognosis should ever be made, however, until forty-eight hours had elapsed from the time of insertion of the tube.

As regards medicinal treatment, Dr. Huber said that it was his practice to keep up the use of bichloride of mercury throughout the course of the disease, whether intubation were resorted to or not. He employed it, in accordance with the views of Dr. Jacobi, in larger doses than those usually recommended; giving from one-sixth to one-half a grain, and in severe cases as much as one grain, in divided doses, during the twenty-four hours. When there was much difficulty in swallowing, he gave it in the form of tablet triturates, of one-fortieth of a grain each, mixed with sugar and placed dry upon the tongue. If there were extensive diphtheritic membranes in the fauces he also employed tincture of iron and chlorate of potassium. In threatened heart-failure he resorted to brandy, caffeine, etc. If the temperature was very high, antipyretics were employed either by the mouth or rectum. Finally, he used the steam atomizer for producing a moist vapor.

Intubation, he went on to say, possessed every advantage possessed by tracheotomy. It could also save many cases in which tracheotomy would not be permitted, as well as many which would die if the latter were performed, especially in children under three

years of age. Out of twelve cases in which Dr. Huber had resorted to tracheotomy, ten had proved fatal. He had also seen many cases in the hands of others in which the results were no more favorable; so that he felt warranted in assigning to intubation a much higher position.

DR. J. O'DWYER read a paper on

FEEDING AFTER INTUBATION OF THE LARYNX,

in connection with which he exhibited various tubes modified to overcome difficulty in feeding. He also showed specimens with the tube in position, and a section of the cricoid cartilage filled up with membranes, except where the tube had left an opening, the form of which was just the shape of the latter.

The difficulty of swallowing, he said, was recognized by all as the most important objection to intubation, and he had long been trying various modifications in the shape of the tube in order to diminish this as far as possible. At first he tried making the heads of the tubes quite small; but, while this rendered it possible for them to slip down into the trachea, it did not make deglutition any easier. The next modification that he made was to increase the size of the head to some extent, and also gave the tube a greater curve, in order to avoid ulceration at the base of the epiglottis. The third modification was to make the posterior surface of the tube longer than the anterior surface, so as to allow the epiglottis to pass over it more completely. Next, he increased the size of the head still further, so that it should fill the cavity of the larynx and prevent fluid and other foreign substances from entering around it. The fifth modification was to make the upper surface of the tube concave, so that it would adapt itself more perfectly to the conformation of the parts; and this modification had the effect of rendering it very easy to remove the tube. With the pattern commonly used, extraction had always proved the most difficult part of the procedure.

The last modification which he had adopted was to give to the upper portion of the tube a double backward curve, in the hope of increasing the facility of swallowing, and this, at all events, had the effect of preventing ulceration of the anterior wall of the trachea, which hitherto had sometimes been quite extensive. Any one, however, who practised intubation at all largely would find it advisable to employ a variety of tubes according to the circumstances of particular cases; and he had lately devised a large, short tube for temporary use in certain instances. The string could be left attached to it, and he thought it probable, on account of the large calibre of the tube, that membranes might sometimes be coughed up through it.

Notwithstanding all his modifications, Dr. O'Dwyer said that he still found about the same difficulty in swallowing present. Solids and semi-solids, as a rule, were taken much better than liquids. Food would not enter the tube if the epiglottis was normal. In a number of instances he had removed the tube in order to give nourishment; but the results were no better than when it was in position. In some cases, particularly when nephritis was present, there was nausea and vomiting, as well as anorexia. Sometimes, however, swallowing was more readily accomplished than before the insertion of the tube, on account of the relief which it afforded to the urgent dyspnœa. As a rule, the longer the tube remained in position, the easier it became to swallow. When the patient was old enough to understand, he always gave instructions that drinking should be done rapidly and that as large a quantity of fluid as possible should be taken at one time. Then, by coughing, the tube could be freed from any of it that might perchance have entered. Sometimes he employed rectal alimentation, but he very seldom had to resort to the stomach-tube.

Passing on to speak of pneumonia, Dr. O'Dwyer said that in his opinion this might arise from (1) the presence of secretions in the lower air-passages; (2) an excess of blood drawn out of the lungs; (3) atelectasis (in the same cases in which there was an extension of the membranes); (4) the presence of a tube either in the larynx or the trachea. He did not believe that food was a cause of pneumonia, as there was no evidence that food had ever been found in the minute bronchi. He had known a patient (an adult female) to wear a tube in the larynx for over ten months, who not only did not have pneumonia, but who in the meanwhile recovered from bronchitis, which she had at the time the tube was put in.

He had lately had constructed two hard rubber tubes designed for all kinds of acute laryngeal stenosis in adults; the smaller one for women and young males, and the larger for full-sized males. The principal difference between these and the metallic tubes was in regard to their weight and the size of the calibre. While a rubber tube weighed only one hundred grains, an adult metallic tube weighed an ounce and three-quarters; and the rubber tube was fully double the calibre of the metallic. As regards the comparative comfort of the two kinds of tubes, one patient found the metallic tube the most satisfactory, while another, who was a syphilitic and had a very sensitive larynx, preferred the rubber. In the latter case the metallic tube produced ulceration, which was not the case with the rubber one, while greater freedom of movement and facility of expectoration were also secured with the latter.

DR. DILLON BROWN read a paper on

STATISTICAL RECORDS OF INTUBATION.

As far as he had been able to ascertain, there had been reported altogether 760 cases of intubation, by 54 different operators; and of these he had tabulated 502 cases. 211, or 27.07 per cent., had recovered. The average age of the children who died was three years and two months, and of those who recovered, four years and one month. In those who recovered, intubation was resorted to at an average period of two days and nine hours after symptoms of laryngeal stenosis had first appeared, and in those who died, at an average period of one day and nineteen hours. In the fatal cases the average time between intubation and death was two days and eight hours; and in those which recovered the average time during which the tube was worn was five days and three and one-half hours. The causes of death he found were given in 339 of the fatal cases. Those who had performed intubation in the largest number of cases were, O'Dwyer, 78 cases; Waxham, 106 cases; Dillon Brown, 84 cases; and Huber, 47 cases.

Unavoidable accidents, Dr. Brown went on to say, were rare, and with the exception of the one of pushing the membranes before the tube, were not important. From the use of too much force false passages had been made in two instances. The slipping of the tube down into the trachea, which had been reported

in several cases, could never occur if a tube of proper size was employed. In two cases the tube had passed into the œsophagus, instead of the larynx; but there was no reason why this mistake should be made if sufficient care were taken. In order to avoid as far as possible the danger of pushing membranes before the tube, he advised that the latter should be pressed well down and held firmly in position with the finger until the obturator had been removed. Coughing up of the tube was a source of danger, but this could, as a rule, be avoided if a tube with a sufficient retaining swell was used. If there were paralysis of the muscles, however, this accident was liable to occur, notwithstanding an ample retaining swell. As to the causes of death after intubation, the extension of the membranes to the bronchi was the most frequent; and he believed that pneumonia, when present, was secondary in character.

Dr. W. P. Northrup read a paper on the

PATHOLOGICAL ANATOMY OF THE RESPIRATORY TRACT AFTER DEATH FROM LARYNGEAL DIPHTHERIA AND INTUBATION.

In a paper on this subject which he read before the Academy in December last, Dr. Northrup said that he had reported eighty-seven fatal cases. Since that time twenty additional fatal cases had occurred at the Foundling Asylum, so that he had now altogether one hundred and seven cases on record. The cause for this large number during so short a period as four months was the occurrence of diphtheria in connection with a fatal epidemic of measles and scarlet fever. The severity of the outbreak was shown by the fact that all the fatal cases had pneumonia, and thirteen of them nephritis. In his former paper he had stated that he had never met with ulcers of the trachea; but in the twenty cases now reported for the first time there were deep ulcers, laying bare the rings of the trachea, in no less than five instances, and he presented the specimens from these cases. He had not as yet met with ulceration of any consequence caused by the head of the tube: — nothing more, in fact, than necrosis of the epithelium. He had never seen any evidence of aspiration pneumonia, as it was called, due to the entrance of milk or other fluid into the finer bronchi.

Dr. Irvin H. Hance read the report of a

CASE OF LARYNGOTOMY AFTER INTUBATION.

It was met with at the Nursery and Child's Hospital, and the patient, who was twenty months old, and suffering from scarlet fever and diphtheria, twice coughed up the tube. After it had been introduced a third time the tube became obstructed, and had to be removed. At this time the child was so exhausted that artificial respiration had to be resorted to for a while. The tube was then inserted for the fourth time, and again it filled up with mucus, and had to be withdrawn. After being introduced a fifth time it again became occluded, and was finally coughed up. The stenosis still continuing, laryngotomy was performed, at the cricothyroid membrane, and complete relief from the dyspnœa was at once afforded. The child died the next day, however, of the scarlatinous disease.

In this case, he said, the tubes were thoroughly tried, and were found to be utterly valueless. Their failure, he thought, was probably due either to the large quantity of tenacious mucus present or to the dislodgment of diphtheretic membrane. It was a question whether tracheotomy should not have been resorted to earlier, before the child had become so exhausted by the existing condition and the repeated introduction of the tube.

In conclusion, Dr. Hance alluded to other cases in which laryngotomy or tracheotomy had to be performed after a trial of intubation. Nine such cases, including his own, had been reported, and among these there had been three deaths and five recoveries, while in one instance the child was still under treatment at the time the report was made. The operation had been performed or advised under the following circumstances: (1) Great irritability of the larynx. (2) When membranes are pushed down before the tube. (3) When the tube became plugged up with dislodged membrane. (4) When there was a return of the dyspnœa with absence of the tube from the larynx. (5) When the tube became wedged in the larynx.

As to laryngeal spasm, he had found that this could usually be controlled with belladonna, nitre and chloral. Practically, the only condition calling for tracheotomy was the obstruction of the tube by membranes, and this was a very rare occurrence. The attempt had been made to remove the membranes with forceps. Finally, he said that he would advise resorting to tracheotomy only after intubation had failed.

In reply to a question of the President, Dr. A. Jacobi, Dr. O'Dwyer stated that in his later cases he had performed tracheotomy after intubation in only one instance. His own experience had been so unfavorable in this operation that he was not disposed to hope for much from it. As to removing membranes with the forceps, the subglottic division of the tube was of such narrow calibre that it was practically impossible to use this instrument, and he had therefore devised a flexible apparatus for this purpose somewhat on the principle of the umbrella probang. He knew of no wedging in the larynx that could occur except such as was sometimes met with when a tube with a very small head was used. Like Dr. Northrup, he had never seen any evidence of the so-called aspiration pneumonia arising from the entrance of food into the bronchi. The secretions, he believed, were the source of the pneumonia that was found after intubation; there being aspiration of these into the finer bronchial tubes. It was due primarily, however, to the presence of the tube, because the latter impaired the patient's power of expulsion; the secretions under these circumstances not being gotton rid of with the same facility as through the normal larynx.

The President said that he was much pleased to hear both Drs. O'Dwyer and Northrup say that they had never seen any reason to believe that pneumonia originated from the presence of food. He would like to inquire of Dr. Northrup whether lobar pneumonia was of frequent occurrence, and if so, whether this was found especially in cases of sepsis.

Dr. Northrup replied that in the 87 cases previously reported by him, 27 were believed to have died from extension of the diphtheritic membrane. In a large proportion of these there were found membranes extending from the tip of the nose to the finest bronchi of the lungs. Bronchial diphtheria, with œdema was a marked feature at the autopsies. Pneumonia, when it did occur, was of late origination. It

affected both lungs, and was lobular, not lobar, in character. In not more than one-fourth of the cases could it be said to have been the cause of death.

DR. CAILLE said that it was too early as yet to speak a final word as to the merits of intubation. Many of the cases published had been reported in such a way as to render them of no practical value. In comparing this procedure with tracheotomy in his own experience, he found that he had performed tracheotomy in 21 cases, with five recoveries, and intubation in 16 cases, with six recoveries. In his cases of intubation diphtheritic membranes were observed on the nares or pharynx in nine instances. Most of the cases were seen in consultation, and, as a rule, intubation was undertaken rather late. He believed that all the patients would have died without surgical interference, and that one who died would have recovered if intubation could have been practised earlier. The cause of death after intubation he had found to be catarrhal pneumonia in a majority of his fatal cases. It was a fact that most of the children who died had taken liquids, and of late he had allowed only solids, cut up fine with rice to allay thirst. Since he had adopted this course his results had been better.

In conclusion, he said that intubation was to be preferred to tracheotomy in the majority of instances. When the pharynx and nares are affected, intubation is preferable, as a rule, to tracheotomy, especially when the after-treatment of the latter cannot be carried out satisfactorily. Tracheotomy is preferable to intubation in some cases, hopeless without operation, provided the surgeon can operate and carry out the after-treatment under the most favorable conditions. These statements apply to intubation with the present style of tubes.

AMERICAN OTOLOGICAL SOCIETY.

TWENTIETH ANNUAL MEETING.

THE twentieth annual meeting of the society was held on Tuesday, July 19, 1887, at the Pequot House, New London, Conn.

MORNING SESSION.

The society was called to order at 10.30 A.M., by the President, Dr. J. S. PROUT, of Brooklyn.

In the absence of the Secretary, Dr. E. E. Holt, of Portland, was elected secretary *pro tem.* Resolutions expressing regret at the absence of the secretary, Dr. J. J. B. Vermyne, who was prevented by ill-health from being present, were adopted, and the secretary of the meeting was directed to forward a copy to Dr. Vermyne.

Dr. John Green, Dr. J. A. Andrews and Dr. J. A. Lippincott were appointed as a nominating and business committee.

The report of the committee of conference with reference to the formation of a Congress of American Physicians and Surgeons, was adopted, and the following resolution was also adopted.

Resolved, That the Society expresses its acquiescence in the general plan for the formation of a congress of special societies as set forth in the printed minutes of the Washington meeting of September 24th.

The naming of the representative and alternate to the executive committee of the congress was left to the nominating committee.

THE EXAMINATION OF THE POWER OF HEARING AND HOW TO RECORD ITS RESULTS,

was the title of a paper read by DR. H. KNAPP, of New York.

This was the report of a committee consisting of Drs. H. Knapp, J. S. Prout and D. B. St. John Roosa. The tests for hearing described were the watch, the voice, Politzer's acumetre, and the tuning-fork. The watch is one of the best means of testing the hearing. A low ticking watch is of service in indicating the lowest degree of hardness of hearing in those cases where the patient has not become aware of the defect. This is, however, not sufficient to measure the higher degrees of deafness. In these cases a loud ticking watch or Politzer's acumetre must supply its place. Each of these instruments must be tested by the physician in his office on a number of normal ears in order that he may obtain a standard. It is a fact that in persons over fifty-five years of age, a low ticking watch may not be heard when placed over the temporal or mastoid bone if the ear is closed, but will be heard if the ear is open.

With reference to the voice, as tests for hearing, the whispered voice, the voice of ordinary conversation and the loud voice are used. Each observer must test his own voice by the acuteness of hearing of normal persons between the ages of twenty and forty-eight years of age. The state of the room as to noise and quiet should always be considered. The tuning-fork over all parts of the skull is heard louder and longer when the ear is closed than when it is open. All tuning-forks are heard longer by air conduction than by bone conduction. Low tuning-forks are heard louder but not longer by bone conduction than by air conduction. Departure from these conditions indicate disease.

DISCUSSION.

DR. SAMUEL SEXTON, of New York. It seems to me that sufficient importance has not been given to the varying conditions of the patients themselves. I find that in cases of chronic catarrhal inflammation of the middle ear, and also in acute forms of inflammation, that there are constantly varying changes in the tension of the drum and in the transmitting mechanism. In these cases the acuteness of hearing changes from hour to hour or day to day. I have noticed that in the morning when the perceptive faculties are active, a patient will hear better than he will later in the day. It is also well known that the vapor tension of the air as well as the temperature has something to do with the transmission of sound. The hearing is better in cold weather than in hot. I think that we shall always find difficulty in obtaining accurate tests for the more interesting cases which come under observation.

DR. D. B. ST. JOHN ROOSA, of New York. I am not inclined to lay such stress as has been done on the variations in hearing from hour to hour, in cases of chronic inflammation of the middle ear. These variations do occur in cases of disease of the middle ear, but I think that they are more marked in disease of the internal ear. In cases of a nervous deafness the condition of nervous exhaustion has much to do with the capacity for hearing.

DR. SAMUEL THEOBALD, of Baltimore. As bearing upon the use of the tuning-fork, I could mention an observation which I have made in a number of in-

stances and which I have been unable to explain. I have noted in certain cases that when I have placed the tuning-fork on the vertex, the patient will hear it louder in one ear, say the right. Then striking the fork again and placing it upon the forehead, it will be heard best in the left ear. This has given me less confidence in the tuning-fork as a differential test between middle ear and labyrinthian troubles.

Dr. H. Knapp, of New York. For practical purposes we must test the hearing as accurately and with as little loss of time as possible. In certain cases of chronic catarrh you get no change in the hearing power by any test. In these cases I think that nothing is to be looked for from treatment. Where, however, by changes of weather or changes in the patient's condition, there is a change in the healing power, we know that there is something to improve. We get not only an estimation of the condition, but we also get a foundation for prognosis and an indication for treatment.

THE SUCCESSFUL REMOVAL OF AN EXOSTOSIS FROM THE EXTERNAL AUDITORY CANAL BY A NEW METHOD,

by Charles H. Burnett, M.D., of Philadelphia.

The patient was a physician, about thirty years of age, in whose right ear the exostosis had been growing for fifteen years, and within the past year it had entirely occluded the meatus and caused deafness. The growth was about one centimetre in diameter, pedículated and attached to the anterior wall of the meatus just within the outer edge of the tympanic bone. Its outer surface was covered with thick and rather insensible skin. After a hypodermic injection into the concha, of fifteen minims of a five per cent. solution of hydrochlorate of cocaine, the outer surface of the exostosis was seized by specially devised bone forceps and a piece of the bone tumor cut off. About one-half of the growth was thus removed in successive pieces. As the blades of the forceps could not enter further into the meatus and get hold of the remnant of the exostosis, a small chisel a few millimetres in width was placed against the attachment and a blow from a hammer on the chisel knocked off the remainder of the growth, en masse. The operation caused very little pain or bleeding. The fundus of the canal and the membrana tympani were covered with a glove finger cast of epithelium. This was removed and the hearing found to be normal. The ear was dressed with a little iodoform and stopped with cotton. There was no reaction and the cut surface of bone on the wall of the meatus at the point of attachment of the exostosis was entirely covered with skin in two or three days. Usually drills impelled by the dental lathe have been used to open the lumen of the canal occluded by exostosis. The novelty in this case consisted in the use of bone forceps devised by the author to remove the growth as far as possible, and then the use of hammer and chisel to complete the opening.

DISCUSSION.

Dr. H. Knapp, of New York. I have taken considerable interest in the removal of exostoses from various canals. To attack them at the apex, with the chisel where they consist of ivory bone is most difficult. The most efficient way, in my experience, is to attack them at the base. Here the bone may be much softer. In the after-treatment cleanliness and antiseptic precautions are of the utmost importance. I think that this is a safe and is the most efficient method of removing these ivory tumors with large bases.

Dr. J. A. Andrews, of New York. I would endorse what Dr. Knapp has stated. Where these osteomata are situated in the orbit, much serious injury may be inflicted upon the brain by the use of the chisel. It would be much easier to fracture the plate of bone lying against the brain in osteoma of the frontal sinus, by attacking the tumor itself than by attacking the bony surroundings of the growth.

THE DIFFERENTIAL DIAGNOSIS BETWEEN AFFECTIONS OF THE MIDDLE EAR AND THOSE OF THE LABYRINTH,

by D. B. St. John Roosa, M.D., of New York.

There has been some difference of opinion as to our ability to differentiate between affections of the middle ear and those of the labyrinth. Many cases usually classed under affections of the tympanum, should be placed among diseases of the cochlea or of the acoustic nerve. The records of seven recent cases were given in detail. These cases were nearly all in the middle period of life, when its cares and troubles are most pronounced. Such patients often exhibit symptoms of nervous exhaustion. These cases may be benefited by the administration of strychnia, arsenic and quinine. Proper hygiene should be employed. The universal use of the watch as a test of hearing occasionally leads to false conclusions on the part of the general practitioner, who discovers loss of hearing by testing with the watch alone. When used alone, I regard the watch as insufficient. When both the watch and the voice are heard badly there is cause for anxiety. Many persons have lesions which cause them to hear the watch and certain other tones badly who can hear the voice well. In the opinion of the author those persons who hear conversation better than the watch, who hear better in a quiet room than where there is a noise, and who hear the tuning-fork better through the air than through the bone, suffer from an affection of the labyrinth or nerve, and not from disease of the tympanum, although the latter may be engrafted upon the previous affection. The general adoption of this view would save a good deal of local treatment of the naso-pharynx and tympanum and greatly simplify and improve our therapeutics.

Dr. Emil Greuning, of New York. Were the cases described by Dr. Roosa benefited by general treatment?

Dr. Roosa, of New York. As far as the aural condition is concerned, I regard these cases as incurable. I think that we can assure these patients that if the general health be looked after carefully that they will never hear so badly but that they can hear in a quiet place. This has a good moral effect. It makes the patient happier, and enables us to dispense with much useless treatment.

Dr. E. E. Holt, of Portland. For several years I have performed experiments with the tuning-fork, but I have not been able to reach the same conclusions as those presented by Dr. Roosa. You may find quite a degree of deafness and still the tuning-fork will be heard longer by air conduction than by the bone. I have seen many cases where bone conduction would be longer than air conduction, and where by treatment the air conduction would become longer. It is difficult to test the hearing properly with the watch

unless it is made with a stop. In my own case I hear the watch very badly. I hear the tuning-fork by air-conduction three or four times longer than by bone conduction. In an ordinary quiet room I can hear all that is said, but in the cars I can hear better than a person with normal ears.

DR. ROOSA, of New York. The case of Dr. Holt would not agree with my experience, which is that of a person who hears well in a quiet room, and who hears the watch badly, always hears worse in the cars than he does in a quiet room.

REMARKS UPON A CASE OF CEREBRAL ABSCESS,

by DR. D. B. ST. JOHN ROOSA, of New York.

The patient, a boy of eleven years of age, came under observation May 4, 1887, with a painful swelling over the right ear. It was said that the boy had had some trouble with the ear two years before, but that there had been no discharge. For three months he had tinnitus aurium and vertigo. One week before he was seen he had pain in the ear, then this swelling appeared. Bone conduction with the tuning-fork was better than aerial conduction. The hearing power of the left ear was normal. Immediately above and in front of the auricle there was a swelling about the size of the walnut. This presented fluctuation. There was a history that previous to admission to the hospital the treatment had consisted in the use of injections and the insufflation of powders. The auditory canal was filled with a white substance which was supposed to be the powder that had been employed. The day after admission the patient was etherized and the abscess opened with the removal of half an ounce of laudable pus. No fistula was discovered. The patient did well for nine days. Nausea and vomiting then set in and the temperature went up to 104°. The patient sank into a condition of coma and died on the tenth day after admission. At the autopsy there was found a cerebral abscess one and one-half inches in diameter, situated in the tempero-sphenoidal lobe one-half inch from the surface of the brain. This was lined with thick membrane. The membrane tympani was perforated and the upper wall of the canal was necrotic. At the junction of the mastoid and squamous bones there was a spot of necrosis one-half inch in diameter. The canal and mastoid cells were filled with caseous material.

(To be continued.)

— Cetti, the Norwegian whose twelve days' fast in Berlin was made the subject of study by Professor Virchow, began on June 13th, a thirty days' fast in London, for "scientific purposes." The performance was brought to an abrupt conclusion by his detection in eating gelatine jujubes, about a half-pound of which were found on his person.

— A suit was recently tried in Brooklyn, says the *Medical Record*, which shows that it is not always safe to speak lightly of a physician. Dr. W. J. Cruikshank recovered a $1,600 verdict, in his suit for $50,000 damages, against William Gordon, the trial of which was brought in the Supreme Court. The doctor asserted that Mr. Gordon went to the mother of a child he was attending, and urged her to secure another physician without delay, as, in his opinion, Dr. Cruikshank had not the skill necessary to attend a sick dog.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, JULY 28, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

A CONTRIBUTION TO THE STUDY OF PERNICIOUS ANÆMIA.

AT the Medical Congress lately held in Wiesbaden, Professor Lichtheim of Berne, in reviewing the present status of medical knowledge respecting that puzzling and obscure affection known as pernicious anæmia, called attention to the facts published last year by Reyher, of Dorpat and Runeberg, of Berlin, in which the coincidence between the manifestations of the disease and the presence in the intestinal canal of various kinds of tænia, seemed to indicate a causal relation between the two facts.

Reyher published thirteen cases of pernicious anæmia, which he regarded as undoubtedly due to the presence of the bothriocephalus latus in the intestines, for all these cases got well after elimination of the parasite.

Runeberg, shortly afterward, published a number of facts of a similar nature. It is worthy of note that previous to these observations there was an outbreak of the same disease among the workingmen of the St. Gothard tunnel, which was occasioned by infection by the ankylostema duodenalis. Prof. Lichtheim, in directing attention to these facts, states as a result of his personal experience, that, although in the majority of cases of pernicious anæmia, followed by autopsy, which had come under his observation, he had been unable to find any tape-worms, yet in a case occurring since Reyher's publication, in which the death was clearly from pernicious anæmia, he found six tæniæ (bothriocephalus latus) in the intestine of the patient. Quite recently, moreover, another case of pernicious anæmia presented itself at his clinic, and here again he discovered in the stools of the patient ova and segments of the bothriocephalus. Since then, he has had nine more cases of the same disease; six of these patients have died, and the autopsy failed to disclose the presence of any intestinal parasites. Lichtheim very sensibly concludes from these experiences that the parasite does not play a constant or well-marked rôle in the etiology of this disease.

He anticipates the objection that the cases in Dorpat and Berlin were not cases of pernicious anæmia. It is, however, a fact that these cases, as well as those occurring in his own practice in connection with the presence of intestinal parasites, presented all the clinical symptoms of the malady. He is therefore led to believe that pernicious anæmia is a "*multiplum*"; that it is the form of anæmia which is the most grave, and may be produced by widely different causes.

Lichtheim has seen two cases of pernicious anæmia which were coincident with affections of the spinal cord. The anæmia was associated both times with degeneration of the posterior columns. He thinks it probable that in these cases the spinal degeneration was a consequence of the pernicious anæmia, rather than a cause. In both instances the diminution of red corpuscles was very marked (500,000 to the cu. mm.) Another case is still under observation, in which the coincidence of pernicious anæmia with tabes dorsalis is clearly shown. "There have been," he says, "the last few years a multitude of facts which go to show the production of spinal affections under the influence of a profound modification of the blood." He recalls to mind in this connection the relation established between syphilis and tabes, and the experiments of Tuczek with certain toxic substances; also the observations of Lépine concerning atrophic paralysis consecutive to pernicious anæmia.

With regard to the treatment of this rebellious malady by transfusions of blood, or saline solutions, Lichtheim does not speak as favorably as Ott and some other authorities. In only one case was improvement noted after the use of intravenous saline injections.

Prof. Jurgensen, in commenting on the above paper, referred to a case of his own: a young man of robust constitution, who, all at once, contracted grave pernicious anæmia. He presented all the symptoms of the disease, and in a very pronounced degree. Temperature from 35° C. to 36° C., for several weeks; pulse only 50 per minute; rapid emaciation; extreme diminution of red-blood globules; dilatation of the heart, etc., Jurgensen thought of a possible infection by the ankylostoma. All other kinds of treatment having failed, he gave twelve grains of the extract of male fern. This dose produced symptoms of intoxication; no segments of tænia were expelled; but, on the other hand, an enormous quantity of *bacterium termo* was found in the stools. The patient immediately recovered his appetite and strength, and two months after was able to return to his home and usual occupation.

Prof. Litten, of Berlin, reported thirteen cases of pernicious anæmia occurring in his hospital service, and eventually proving fatal. The autopsy of these patients gave negative results as far as the presence of any intestinal parasites was concerned. He, therefore, agrees with Lichtheim and Jurgensen that there is no constant etiological connection between pernicious anæmia and the presence of tæniæ in the intestines.

THE TREATMENT OF BURNS.

The treatment of burns of the first and second degrees, when not of too large extent, is generally a matter of no great difficulty, such injuries healing readily by rest and the most simple applications. Burns of the third degree, even when not implicating a large surface of the body are very slow to heal, and cause great disturbance of the functions of the skin and of the entire system.

Prof. Mosetig writes in the *Wiener Med. Press*, Nos. 2 and 3, 1887 (and here we are indebted to the June number of the *Journal of Cutaneous and Genito-Urinary Diseases*), that he has treated forty-eight cases of severe burns with iodoform, and highly praises this mode of treatment. The action of iodoform is twofold; it is both analgetic and antiseptic. In Mosetig's hospital, patients treated by iodoform, lie quietly in bed, free from pain, they recover more quickly, with less loss of strength, and have smoother scars than when otherwise treated. If life cannot be saved in any given case, at least euthanasia is secured. Although the danger to life from oligochythæmia and nerve shock is not lessened by iodoform, it does lessen the danger of sepsis. In employing iodoform Mosetig so employs it that only a small amount is used. He either does not apply the powder at all as such, or he dusts it lightly over those parts that have been deeply burned, and over which the skin is in a parchment-like condition. He advises iodoform gauze compresses, not the dry preparations which are found already made in the shops, holding much loose iodoform powder, but the kind which he himself first recommended, and which are prepared by impregnating bandage gauze which has been cleansed and freed from fatty matter, with an iodoform solution in ether.

Before being applied, any blisters or bullæ must be opened, and their walls cut away and all foreign substances cleansed by absorbent cotton wet in a one-half per cent. solution of salt. Several thicknesses of the iodoform gauze are then cut to fit the burned part, and applied dry, so as evenly and entirely to cover in the region. Over this is to be spread an equally large sheet of gutta percha paper; care being taken to avoid wrinkles; and finally over all a thin sheet of absorbent cotton encircling the whole region of the body, and the whole secured by turns of a roller bandage.

This is designed to be a permanent dressing, and is to be kept on as long as cleanliness permits, and the temperature does not furnish an indication for its removal.

Simple wetting of the dressing is not an indication for changing it, but should the outer bandage become offensive, it should be changed without moving the others. The iodoform gauze and gutta percha sheet should not be removed until the end of the second week.

Should fever make its appearance, and point to septic trouble as a cause, the probability is that demarcation has taken place, and the burn-slough is

coming away, and there is retention of the secretion of the wound. The retention of pus must be sought for, and the slough removed with forceps and fingers; and fresh dressing applied as before.

The gutta percha dressing is said to be very necessary, and should never be omitted, for should the gauze dry and stiffen upon the burn it can only act injuriously.

By means of this permanent iodoform dressing, the contact of air and infection is prevented; and healing takes place in burns of the second degree under the first bandage. In burns of the third degree, the slough is thrown off with slightly marked secretions, but when the latter is not the case, healing takes place by granulation in relatively shorter time, and the scars are flatter and smoother than those resulting from the healing of non-aseptic wounds.

In burns of the face, Mosetig recommends the use of an iodoform salve (1 to 20), and over it the application of a gutta percha mask.

MEDICAL NOTES.

— Passed Assistant Surgeon John Guitéras, United States Marine Hospital Service, reports under date of July 21, total number of cases of yellow fever at Key West to date, 135; deaths, 35. A majority of the new cases are native children. One death occurred from yellow fever on the 15th inst., at Egmont Key, Florida, (refuge station.)

— The *Lancet* says: "We make no secret of our deep dissatisfaction, extensively shared by the profession, with the dispensation of Jubilee honors. Apart from the reasonable expectations of our own profession, the dispensation is exceedingly disappointing and unworthy of the occasion." Professor Gairdner, of Glasgow, has declined the knighthood tendered him.

— Dr. John Vansant of the United States Marine Hospital at St. Louis, has succeeded in taking a successful photographic negatives by means of the light emitted from twelve fire-flies. The insects were placed in a three ounce bottle, having a piece of fine white bobinet stitched over its mouth. The average duration of the flash of each insect is half a second, and the luminous area on the abdomen is about one-eighth of an inch square. The time of exposure was that of fifty flashes, as counted by the operator, who claims to have the first picture ever produced by the light emitted from a living human organism.

— The wife of an Illinois farmer had six toes on each foot and six fingers on each hand. The farmer became incensed at his wife when his children were born and found to be similarly equipped with toes and fingers. Recently the birth of the third child occurred, with the same peculiarities. In a fit of anger the husband struck the poor woman over the head with a hammer, and she died from the effects of the blow. The murderer was placed in jail, but it is believed he will be lynched. So runs the newspaper despatch.

Instruction in physiology in the public schools will teach the rising generation of males the consequences of marrying supernumerary digits or other physical or mental peculiarities. Male adults will not only be expected to know their own taste in these matters, but also the consequences of their acts, and there will be no possible excuse for such an act as that of the Illinois farmer.

— Professor Charcot in a recent letter addressed to Dr. Merlotti, an Italian physician, alludes to the danger to morals and health which are likely to result from public exhibitions of hypnotism. The induction of the hypnotic condition, he says, is by no means as inoffensive as we are asked to believe; it approximates so nearly to the hysterical neurosis that under certain circumstances it may, like the latter, become freely contagious. If medicine in the cause of science has taken up this condition, its production should be restricted to the narrowest limits, and it ought never to be allowed in profane hands, capable of misusing it to the public detriment.

— An English contemporary gives the following statistics, as showing the past and present revenue derived from the duty on proprietary medicines in Great Britain. In 1865 the receipts under this head were £55,333. Ten years later the amount had increased to £114,323, and last year it was upwards of £171,000. Although the quantity of patent medicines placed upon the market did not increase in so large a proportion between 1876–86 as between 1875–85, the public demand would appear to have been more general from the fact that the number of vendors increased by 35 per cent. during the recent, as against 26 per cent. of the earlier period. The label duty being equal to one-eighth of the value of the article stamped, we have a ready means of estimating the approximate annual expenditure in patent medicines. Within twenty-one years it has risen from £497,997 to £1,611,639.

— The *Journal* has already referred editorially to the reported discovery by Dr. Edington of Edinburgh, of a definite bacillus, provisionally termed the bacillus scarlatinæ, obtained from the blood and desquamation of scarlatinal patients, a claim at variance, as will be seen, with Dr. Klein's recently published researches showing the streptococcus scarlatinæ to be the cause of the disease. The Medico-Chirurgical Society of Edinburgh, has appointed a committee to investigate the method and repeat the experiments conducted by by Dr. Edington with a view, if possible, to the speedy corroboration of the important discovery. The Committee consists of Professors Grainger Stewart (President), Greenfield, and Drs. Carmichael, Hare, Philip, and Woodhead. The Society arranged a discussion on scarlatina for Wednesday, July 20th, when it is hoped the Committee might have some preliminary reports to offer.

— Dr. E. D. d'Oliveri in *La France Médicale*, June 21, 1887, calls attention again to the superiority of iodide of ammonium over the salts with other bases. Rabuteau, in 1872, said that iodide of ammonium was less stable than the other iodides, and more rapid in action, and therefore to be preferred in cases of grave syphilis where prompt and energetic action was necessary. Oliveri says that the chief hindrance to the use of this drug in France has been the impurity of its commercial preparation and its chemical instability. Meynet, a Parisian pharmacist, is said to have produced an aqueous solution of the strength of one gram to the teaspoonful, which is at once pure and stable.

— Sir Andrew Clark in the *Lancet*, June 11, 1887, describes a speedy and sometimes successful treatment of hay fever by the application through the nostril to the naso-pharyngeal cavity on a laryngeal brush of a mixture thus composed: glycerin of carbolic acid, one ounce; hydrochlorate of quinine, one drachm, and one-thousandth part of perchloride of mercury, heat being required to dissolve the quinine. If there is much mucus in the nostrils, cleanse them by means of a douche of warm water containing boroglyceride, in the proportion of an ounce to the pint. The brush is to be loaded with the mixture but not to overflowing; the left hand steadies the left side of the patient's head and the thumb controls the shape of the nostril by being applied to the top of the nose. The brush is carried first to the upper part of the nasal cavity, and then through the posterior nares to the pharynx. If the symptoms are severe the brush may need to be applied to the pharynx through the mouth. The application is painful to the patient, and of this fact he should be forewarned. But the pains, smarting and occasional bleeding pass off in half a day. Sometimes one application has stopped the disease for a whole season, and four times within the author's own knowledge it has never reappeared. The treatment may be renewed on alternate days or each third day, but two or three applications are enough to insure the chance of success.

NEW YORK.

— Dr. Moreau Morris, in charge of the extra service of summer physicians reported to the Board of Health, July 20th, that during the first week of the service the members of the corps inspected 4,738 houses, inhabited by 32,710 families, and distributed 2,459 circulars imparting sanitary information, and 673 tickets for the St. John's Guild Floating Hospital excursions. They prescribed for 867 cases of sickness, of which 475 were diarrhœal in character.

— In the reorganization of the Board of Health recently adopted by the Commissioners, Dr. R. S. Tracy was made Chief Inspector in the Sanitary Bureau, Dr. Cyrus Edson Chief Inspector of Food, and Dr. William Bullard Chief Inspector in charge of the work of the Sanitary Police.

— Dr. Joseph C. Hutchinson, the most eminent general surgeon of Brooklyn, N. Y., died at his residence in that city, July 17th. He was born at Old Franklin, Howard County, Missouri, in 1827, and graduated from the Medical Department of the University of Pennsylvania, in 1848. After practising for four years in his native State he removed to Brooklyn, where he remained in active practice up to the time of his last illness. He devoted himself principally to surgery, and won for himself a national reputation. He founded the Brooklyn Orthopædic Infirmary, and for many years was its chief surgeon. In 1860, he was elected Professor of Operative and Clinical Surgery in the Long Island College Hospital, a position which he held for seven years, and not long since he was made President of the collegiate department of that institution, in place of the late Dr. Dudley. For three years, beginning in 1873, he served as Health Commissioner of Brooklyn, and somewhat earlier than this, he was elected President of the King's County Medical Society. He was one of the founders of the New York State Medical Association, and was the first President of the Fifth District Branch of that Society. Dr. Hutchinson was one of the foremost citizens of Brooklyn, and was universally held in the highest esteem.

Miscellany.

A CYCLE OF TUBERCULOSIS INFECTION.

Besides cases of infection of tuberculosis in the human subject as described in Dr. Knight's paper in another column of this Journal, well authenticated instances have not been wanting of transferrence of tuberculosis from man to animals and vice versa. The domestic fowl has been known to prove an easy prey to this species of infection, as when the sputum of a consumptive patient was cast into a barn-yard, infecting a whole flock of hens. The following case, reported by Dr. Lamallerée, of the congress of the French Scientific societies, in Paris, and recorded by the French Correspondent to the *Therapeutic Gazette*, shows the chain of contagion of tuberculosis (1) from man to man, (2) from man to animal, (3) from animal to man.

In 1872 a young man liberated from military service after he had been a prisoner of war, came to a small village, where he settled as a woodcutter. Although suffering from bronchitis, he married a young girl of the locality, but soon after he was taken with hæmoptysis, and died within a year after his marriage, leaving a child rather delicate. The widow, who had been a strong, healthy girl, gradually became consumptive, so that in 1885 she had cavities in her lungs, profuse expectorations, and now she presents all the symptoms of an approaching end. Dr. Lamallerée was recently called upon to see a neighbor of the widow just mentioned, a young women whose antecedents could not lead him to suspect tuberculosis. The patient, nevertheless, was found to suffer from incipient phthisis. After long questioning, it was ascertained that within some four months she had eaten eleven chickens bought from her neighbor, and as her strength was failing she had roasted them very slightly, hoping to thus get more nourishment. From her

house the doctor stepped into the widow's whose case he knew well, to ascertain how the hens were fed, how they had died, and whether they were in the habit of absorbing sputa. On this point he received prompt satisfaction. As he was walking into the house he heard the widow have a fit of coughing, and immediately a legion of chickens ran in, as they are wont to when hearing the voice of one who feeds them, and began to fight around the bed for the consumptive's sputa. One of the hens having died the same morning, the doctor found in the animal seventeen soft tubercules; the liver was honeycombed with them, and the liquids contained many bacilli.

THE DEATH POINT OF MICRO-ORGANISMS.

AN important paper by Dr. Geo. M. Sternberg, in the July number of the *American Journal of the Medical Sciences*, gives the results of his experiments as to the temperature necessary to destroy the various known micro-organisms. His conclusions are as follows:

(*a*) The temperature required to destroy the vitality of pathogenic organisms varies for different organisms.

(*b*) In the absence of spores, the limits of variation are about 10° Centigrade (18° F.)

(*c*) A temperature of 56° C. (132.8° F.) is fatal to the bacillus of anthrax, the bacillus of typhoid fever, the bacillus of glanders, the spirillum of Asiatic cholera, the erysipelas coccus, to the virus of vaccinia, of rinderpest, of sheep-pox, and probably of several other infectious diseases.

(*d*) A temperature of 62° C. (143.6 F.) is fatal to all of the pathogenic and non-pathogenic organisms tested, in the absence of spores (with the single exception of *sarcina lutea*, which, in one experiment, grew after exposure to this temperature).

(*e*) A temperature of 100° C. (212° F.) maintained for five minutes destroys the spores of all pathogenic organisms tested.

(*f*) It is probable that some of the baccilli which are destroyed by a temperature of 60° C. are from endogenous spores which are also destroyed at this temperature.

ALBUMINURIA IN HEALTH.

PROF. GRANGER STEWART has recently made an important communication on the above subject to the Royal Society of Edinburgh, based upon a large series of examinations of the urine of persons supposed to be healthy, the tests being carefully made with nitric and picric acids. According to the *Medical Press*, Professor Stewart examined the urine of 407 persons, and discovered albumen in 129, that is, in 31 per cent. Care was taken to avoid such fallacies as might arise from the presence of gonorrhœa, spermatorrhœa, and such like. Of 205 soldiers, 77, that is, 37.56 per cent., had albumen. Of 74 civilians, 10.8 per cent. had albumen. Of 40 pauper children in one of the city poorhouses, 17.5 per cent. had albumen, and of 40 adult paupers of about sixty years of age, 67.5 had albumen.

The following table shows the per cent. of persons having albuminuria before and after breakfast:

	Before Bkfst.	After Bkfst.
Soldiers	15.6%	40.6%
Old Men	37.5%	67.5%
Children	12.5%	17.5%
Children (2d group)	14.6%	20.8%

Professor Stewart also drew attention to the effect of exercise and exertion. Thus, of a party of soldiers, before taking exercise, 29 per cent. had albuminuria, and on their returning from an eight miles' march, the percentage was lowered to 19. Again, of a party of soldiers, 15.6 per cent. had albuminuria before breakfast, 40.6 per cent. after breakfast, and 28.1 per cent. after a march of eight miles. When more severe exertion was undertaken, the results were different. Thus, before commencing coaling duty (that is, the carrying of and distributing coals from the basement to the upper parts of Edinburgh Castle), soon after breakfast, 44 per cent. showed albuminuria, and after they had finished the work, the percentage was found to be raised to 64 per cent. Of band boys, playing wind instruments, he found the percentage having albumen to be 20.8, while in other boys in the same institution not so employed, the percentage was 8.3; but, after one hour's playing, the band boys showed a diminished percentage of 12.5. Of 21 boys in the orphan hospital, 19 per cent. showed albumen before taking a cold bath, and after the bath, the percentage was increased to 23.8. Professor Stewart draws the following, among other conclusions: That there is no sufficient proof that albumen is normally discharged from the human kidneys. That albumen is much more common among presumably healthy people than was formerly supposed, tests having demonstrated its presence in nearly one-third of the population. That the frequency of albuminuria increases as life advances. That it is more common among those whose occupations involve arduous bodily exertion than among those who lead easy lives. That albumen frequently follows the taking of food, especially of breakfast, which, more than any other meal, increases the amount of albuminuria. That moderate muscular effort rather diminishes than increases albuminuria. That it is often induced by violent and prolonged exertion. That cold bathing produces or increases it in some individuals. That the existence of albuminuria is not of itself a sufficient cause for the rejection of a proposal for life insurance.

PUERPERAL INSANITY.

AN interesting discussion on the above subject took place in a recent meeting of the Washington Obstetrical and Gynecological Society, introduced by a paper by Dr. F. C. Fernald. The paper and discussion are to be found in the *American Journal of Obstetrics* for July. Dr. Fernald's conclusion as to the etiology of the affection was as follows: —

"I would say that a hereditary neurotic constitution is the predisposing cause, while the exciting cause is physical depression, resulting from a number of factors of which labor is only one, some of the remainder having usually been acting for a shorter or longer time before delivery."

The chair called attention to the comparative percentages of recoveries in the three forms of insanity — pregnancy, parturition, and lactation. A table presented by Dr. Adams showed that these forms of disease are more frequent and more favorable in reverse of the order named. The farther the attack is removed from the period of pregnancy, the greater the

probability of recovery and the shorter the duration of the disease. The table shows, also, that the average age of the cases of insanity of parturition and lactation is less than that of the cases of insanity of pregnancy, but the difference is not sufficient to account for the lessened mortality and duration of the other classes.

Dr. W. W. Godding said that the three forms of puerperal insanity are frequently confounded in statistics. They, however, seemed to him to be different conditions, all, perhaps, dependent upon an exalted nervous state, but insanity prior to the birth of the child appears to be of an inherited type, the pregnancy being merely the exciting cause.

The insanity of parturition is the only true puerperal insanity. The conditions at this time are favorable for an outbreak; there is exhaustion of the vital powers, anemia and nervous irritability.

He thinks there is good reason to differentiate puerperal insanity from ordinary mania or melancholia. In puerperal mania there is an intensity of type. The patients exhaust early, and when there is no inflammation of the brain, exhaustion is the danger. For this reason the feeding of such patients is of the greatest importance, and he would advise easily digestible foods, as eggs and milk with wine, etc. Fatal cases usually die in two or three weeks, but if they live beyond three weeks, there is a good chance of their getting well, though they may run into dementia.

Speaking from memory, he would have said that the death-rate was about five per cent. in those cases which were uncomplicated with hereditary insanity, and from eight to ten per cent. in women from all causes. From hastily prepared figures which he had brought with him, drawn from the records of St. Elizabeth, he finds the death-rate twenty per cent., and that only twenty-five per cent. are cured — a sad commentary on the curability of the disease. Some cases admitted under puerperal insanity have gone on to chronic mania, and their death from ten to twenty years after ought hardly to be said to result from puerperal mania. Such statistics are deceptive and misleading.

A point which he has often observed is that women, even in the best walks of life, make use of the most horrible profanity and obscenity during these attacks.

While it is probable that the origin of the trouble is in the genitalia, pyemia is not the cause, in his opinion. The condition is one of exhaustion, the brain being irritated, not inflamed. The pulse is usually soft and not above one hundred, the temperature only slightly raised, and no evidences of pyemia.

Dr. Godding remarked that he has always fought against the admission of such cases into an asylum. The stigma attached to this proceeding, and the critical condition of the health of the woman should, he thought, lead the general practitioner to carefully consider the circumstances in each case before he advised such removal.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 16, 1887.

Deaths reported 3,628: under five years of age 2065; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1,389, consumption 326, lung diseases 130, diarrhœal diseases 1,125, diphtheria and croup 103, typhoid fever 39, measles 34, malarial fever 32, whooping-cough 20, cerebro-spinal meningitis 16, scarlet fever 14, puerperal fever five, erysipelas two. From measles, New York 12, Philadelphia nine, Lowell four, Boston, District of Columbia, Pittsburgh and Milwaukee two each, Brooklyn one. From malarial fever, New York 11, New Orleans seven, District of Columbia and Pittsburgh four each, Philadelphia and Worcester two each, Brooklyn and Boston one each. From whooping-cough, Philadelphia and Boston five each, Baltimore three, New York and Nashville, two each, Richmond, Pittsburgh and Milwaukee, one each. From cerebro-spinal meningitis, New York seven, Milwaukee two, Richmond, Boston, Baltimore, District of Columbia, Charleston, Lowell and Brockton one each. From scarlet fever New York seven, Brooklyn, Boston, Baltimore Pittsburgh, Worcester, Lawrence and Salem one each. From puerperal fever, Brooklyn three, Philadelphia two. From erysipelas, New York and Philadelphia one each. From small-pox (New York) one.

In the 21 cities and greater towns of Massachusetts, with a population of 883,525 (population of the State 1,941,465) the total death-rate for the week was 26.37 against 27.12 and 21.77 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending July 2d, the death-rate was 18.1. Deaths reported 3,207: infants under one year of age 807; acute diseases of the respiratory organs (London,) 199, measles 156, whooping-cough 136, scarlet fever 38, diphtheria 22, fever 22, small-pox (Cardiff) two.

The death-rates ranged from 9.4 in Derby to 29.2 in Manchester; Birmingham 15.9; Hull 16.7; Leeds 18.7; Leicester 14.2; Liverpool 21.4; London 16.6; Norwick 20.8; Portsmouth 12.5; Sheffield 19.1; Wolverhampton 19.4.

In Edinburgh 16.9; Glasgow 19.9; Dublin 29.4.

The meteorological record for the week ending July 16, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, July 16, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 16, 1887, TO JULY 22, 1887.

By par. 43 S. O. 162 A. G. O., July 15th, so much of par. 1 S. O. 156 c. s., A. G. O., as directs Capt. Jno. de B. W. Gardiner, Assistant Surgeon United States Army, to report for duty at Fort Washakie, Wyo., is revoked.

BARNETT, R., captain and assistant surgeon. Sick leave still further extended six months on account of sickness. S. O. 162 A. G. O., July 15, 1887.

By par. 42, S. O. 162, A. G. O., July 15th, so much of par. 1 S. O. 156, c. s, A. G. O., as relieves Capt. Geo. H. Torney, Assistant Surgeon, United States Army, from duty at Fort Monroe, Va., is revoked.

TAYLOR, A. W., captain and assistant surgeon. Now at Fort Laramie, Wyo., is ordered for temporary duty at Fort Robinson, Neb. S. O. 162, A. G. O., July 15, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING JULY 23, 1887.

FESSENDEN, C. S. D., surgeon. Granted leave of absence for thirty days on account of sickness, July 18, 1887.

MEAD, F. W., passed assistant surgeon. Granted leave of absence for thirty days, July 19, 1887.

YEMANS, H. W., passed assistant surgeon. Granted leave of absence for thirty days, July 23, 1887.

BROOKS, S. D., passed assistant surgeon. Promoted and appointed passed assistant surgeon from July 1, 1887. July 21, 1887.

WHITE, J. H., assistant surgeon. To proceed to Washington, D. C., as escort to an insane seaman, July 18, 1887. Ordered to examination for promotion, July 23, 1887.

WATKINS, R. B., assistant surgeon. Leave extended fourteen days, on account of sickness, July 20, 1887.

MAGRUDER, G. M., assistant surgeon. To proceed to Galveston, Tex., for temporary duty, July 21, 1887.

RESOLUTIONS OF THE SPRINGFIELD MEDICAL SOCIETY ON THE DEATH OF DR. JOHN S. BAGG.

The Springfield Society for Medical Improvement, through its committee appointed for the purpose, present the following resolutions upon the death of the late Dr. John S. Bagg.

Resolved, That in the death of Dr. John S. Bagg, the profession has lost one of its most promising members; one who possessed unusual qualifications for the practice of his profession; who was the very soul of honor in his relations with other physicians, who despised all pretense, who did what he had to do thoroughly and well; who frowned upon all professional work that was not strictly honest and honorable; seeking for himself only that professional reputation and reward which ultimately attends upon real merit.

Resolved, That the community has been deprived of a citizen who always manifested a warm interest in all public affairs, and who contributed liberally to the artistic and charitable enterprises of the city, which he had but recently made his home.

Resolved, That the Springfield Society for Medical Improvement, of which the deceased was an honored and a beloved member, extends its profound sympathy to his family, and that a copy of these resolutions be sent to them and to the *Boston Medical and Surgical Journal*.

G. S. STEBBINS,
F. W. CHAPIN,
DAVID CLARK, } *Committee.*

ON THE FREQUENCY WITH WHICH LEAD IS FOUND IN THE URINE, AND ON CERTAIN POINTS IN THE SYMPTOMATOLOGY OF CHRONIC LEAD POISONING.[1]

BY JAMES J. PUTNAM, M.D.

THAT some of the characteristic symptoms of spastic paraplegia are occasionally due to lead-poisoning can, I think, be established beyond much doubt, though the fact is not generally recognized, all the writers on the subject, from Tanquerel down, speaking of the paralysis of the legs as characterized by atrophy and muscular relaxation, like that of the upper extremity, not by rigidity and exaggerated deep reflexes. The former condition is certainly the rule, and for the simple reason that the paralysis of the legs, like that of the arms, is usually due to peripheral neuritis. Brissaud, for example, takes this view, in his recent and excellent monograph on the toxic paralyses,[13] yet, while calling attention to the fact that the so-called deep reflexes are habitually diminished or lost, he says that in exceptional cases they are exaggerated, owing as he thinks, to a sort of associated condition of spinal irritation.

Brissaud also points out that the interesting observations on the effects of poisoning by the different species of lathyrus, in the southern countries of Europe, and especially the investigations by Bouchard and Proust, show that the typical symptoms of lathyrism consist in spastic paraplegia, with exaggerated deep reflexes and without marked sensory symptoms. Ergot[14] also causes pronounced spastic paraplegia as its typical sign of its poisonous action.

Besides this spastic form, there is a flaccid form of lathyrism paralysis which Brissaud thinks is perhaps of peripheral origin, and may justify the ranking of this poison under the same head with lead, arsenic and alcohol. The question is whether these latter agents also, or at any rate lead, besides the flaccid paralyses or peripheral origin may not sometimes cause a typical spastic paraplegia.

I am well aware that the presence of ankle-clonus and exaggerated knee-jerk cannot be taken as proof of the existence of spinal sclerosis. They are found exaggerated in hysteria and neurasthenia, acute and chronic, and I have seen both quite recently in two cases of severe anæmia, one following rheumatism and one of unknown origin. They may, in short, indicate only a functional, nervous hyperexcitability. Such may have been the origin of the symptom in a case reported by Dr. Dercum, of Philadelphia,[15] where a very large amount of lead was found in the urine, and which was characterized otherwise by the following symptoms; loss of strength and weight for two years; great nervousness; insomnia; severe itching of the skin; numbness of the right arm; indigestion; cramps in the abdomen; exaggeration of the knee-jerk.

Finally, Möbius, and Strümpell have reported two cases supposed to be instances of multiple neuritis, in which this symptom was present, and perhaps another example of this kind is furnished by the following case, which was reported by Dr. S. G. Webber[16] as probably an instance of lateral sclerosis due to lead, but which seems best interpreted as peripheral polyneuritis with exaggerated knee-jerk.

"Female patient, married, twenty-three years old; numbness and pain below the elbows and knees, for three months past; swelling of legs; at time of examination, paralysis of feet in extension, with pain on passive motion; delayed sensation from feet; complete paralysis of extensors of wrist and fingers, and incomplete paralysis of the rest of the muscles of the arm below the elbow; diminution or loss of Faradic reaction; urine contains considerable lead; knee-jerk very greatly exaggerated, improvement under treatment."

Setting aside for the moment the question whether we are justified in assuming that the pronounced exaggeration of the knee-jerk and the presence of the ankle-clonus in these cases is really due only to a general nervous erythism, or to an irritability of the spinal cord, let us glance at the remaining evidence that this symptom and other signs of spastic paraplegia are seen in typical lead-poisoning and in the cases where lead was found in the urine.

The first case is that of T. C., a stone-cutter, from Quincy, who came to the Massachusetts General Hospital on May 5, 1887. He reported that he had a chancre four or five years ago, followed he thinks, by secondary symptoms, and used also to drink a good deal of liquor, but not for three or four years. Except for this his previous health had been good, and he had not at all the appearance of a person suffering from the cachexia of alcohol. For three or four years he has not felt well, and has been subject to "jumping" pains in the head, back and legs, especially about the knee; also pains in the abdomen, not always attended with indigestion.

Three months ago he began to lose power in the extensors of the fingers and thumb of the left hand. This increased steadily but is still incomplete, the little finger being extended fairly well; the others in the order in which they follow. The extensores carpi radialis and ulnaris are both deficient, the ulnar extensor, as is usual in lead paralysis, acting the best. There is slight tremor on attempted extension of the fingers. The muscles of the right arm are in a similar but much less serious condition; that is, there is a slight tremor and incomplete extension of the fingers. The electric examination shows loss of Faradic reaction in the extensor communis digit of the left arm, and R. D. at three M. A. The Faradic reaction of the flexors of the left arm, and of both flexors and extensors of right arm is normal. The knee-jerk is exaggerated on both sides, though more left than right, and there is a trace of ankle-clonus, increased by "reinforcement." There is no marked spastic gait, but at times his legs feel stiff.

The second case is as follows: Male patient; works at grinding up old articles of manufactured rubber (in the making of which litharge is used); has had severe abdominal pains for the past four months; constipation; tenderness on pressure over the abdomen; fatigue in walking; insomnia, due he thinks to the pains; yellowish cast to conjunctiva and complexion; *marked blue-line* on the gums; exaggeration of the knee-jerk, and trace of ankle-clonus.

I am indebted to Dr. R. T. Edes for the notes of the following cases:

(1) Jennie C., aged twenty-two. Sharp pains in legs, with numbness and inability to walk; creeping

[1] Concluded from page 76.

sensations in the hands; muscular tremors; exaggerated deep reflexes; lead in urine.

(2) John D., aged twenty-six. Pains in thighs, and numbness of legs; staggers a little in walking and standing with eyes closed; patella reflex exaggerated; ankle-clonus. No syphilis. In this case the urine was not examined for lead, but it is some evidence in favor of its presence that the patient worked in rubber, an industry in which lead is largely used, and which has furnished me with a typical case of spastic paraplegia, and two cases of typical lead-poisoning.

Finally, we come to the instances of typical spastic paraplegia and allied cases, where lead was found in the urine.

Of these the first is the case of a plumber, who besides a typical spastic paraplegia, which was of a year and a half's standing, had considerable impairment of hearing and eyesight, of the same duration, slight but distinct trembling or twitching of the lips and muscles of the face, in talking, and looked pale and rather sickly.

In the second and third cases the symptoms of spastic paraplegia were also well marked. A certain degree of support to the motion of causation by lead, besides the finding of lead in the urine, was furnished by the fact of considerable improvement, partly under treatment, partly without treatment, so that one of the patients was eventually able to resume work though not cured.

The significance of this improvement as a sign of poisoning rather than of progressive degenerative disease could easily be overrated. Such cases do sometimes improve, at any rate, for a time, and in one of these the improvement seemed more or less independent of the taking of potassic iodide. Still, improvement for any considerable length of time is not common in the run of cases of chronic myelitis of any form. It is also worthy of note that, as Tuczek [17] has pointed out, the spinal sclerosis due to ergot, which gives rise to these same symptoms of spastic paraplegia, shows a rather remarkable tendency to remain without progressing, though without much improvement, when the patients are withdrawn from the influence of the poison.

In a fourth case the patient was a painter, and besides his spastic gait and exaggeration of the deep reflexes, he suffered from attacks of dizziness and increased frequency of micturition. A small trace of lead was found in the urine. The symptoms seemed to indicate an extension of the disease beyond the limits of the spinal cord.

In a fifth case the spastic symptoms were accompanied by signs pointing to multiple sclerosis; ataxia of arms and legs; almost universal paræsthesia and anæsthesia, especially in patches; great impairment of muscular sense; excessive hyperæsthesia to contact with hot or cold objects; transient hemiparetic attack; tremor on effort. These was exaggerated knee-jerk but no ankle clonus; no cachexia suggesting lead.

On the other hand, in three typical cases of spastic paraplegia, one of them complicated with atrophy of the muscles of the hands and arms without contracture, no lead was found. The test for lead was also applied, and none found in another case, which might be classed under the head of multiple sclerosis, but this was evidently not a case of sclerotic inflammation of the ordinary type, but rather of some hereditary degenerative process, the patient being a young girl and the case peculiar in several respects.

I am by no means prepared to assert that a clear case is made out for the causation by lead of typical chronic spastic paraplegia, or of ataxic paraplegia. I would only claim that the cases I have reported indicate that as a direction in which to look in the future. The fact that ergot and lathyrus, cause the same group of symptoms, and that syphilis leads to another form of spinal sclerosis, rather encourage us to look favorably upon the evidence adduced, and what we already know of the pathology of lead-poisoning does not make such a connection intrinsically improbable.

It is perfectly true that the great weight of pathological evidence is in favor of the view that the typical lesion of lead paralysis is an inflammation not of the spinal cord, but of the peripheral nerves, but it is equally true that the nutrition of the spinal cord is sometimes more or less grossly impaired (in six out of fourteen cases, as Dr. Birdsall [18] made out from an analysis of autopsies, published up to 1881. See also Schultze,[19] Oppenheim,[20] Brissaud,[21] and Robinson.[22])

Again, although it is true that typical *outspoken* lesion in lead-poisoning is usually confined to the peripheral nerves, and even to the peripheral extremities of the peripheral nerves, yet, as is pointed out by Oswald Vierordt, the writer who has spoken the latest word on the subject,[23] lead paralysis is, after all, a "system" disease, not a general neuritis, and as such probably affects in some degree all the segments of the motor system of which those special nerves form a part. The injury to the spinal cord probably effects no more, in most cases, than an impairment of its normal nutritive influence upon the peripheral nervous and muscular apparatus. If this opinion is correct, the involvement of the spinal cord may be a matter only of more or less, and it is not inconceivable that the antero-lateral pyramid tracts of the spinal cord, though not forming a part of the lower nerve segment (Gowers) which is primarily involved in lead-poisoning, might be secondarily involved, as so often happens, in progressive muscular atrophy; or might be primarily and separately attacked; or, finally, the disease in them might be due to thickening of the vessels so common in lead-poisoning. Such reasoning is, however, of secondary importance in the absence of more definite clinical and pathological evidence.

In contrast with these cases where the motor spinal tracts were involved and where lead was so often present, I would mention that in three cases of local ataxia; five cases of progressive muscular atrophy; and one which was a case of either acute symmetrical neuritis, or of polymyelitis of the adult, no lead was found.

The next group of cases examined for lead is characterized by more or less distinctly localized cerebral or cerebro-spinal symptoms. This group contains seven cases, in all of which lead was found. Three of these cases may be excluded because the disease was fairly assignable to other causes. The other cases

[23] Arch. fur Psych. und Nervenkr. xviii, I, 1887.

are not sufficiently alike to make it worth while to consider them together, and I will therefore postpone the enumeration of them to a future time.

The next group is that of the epileptic cases. This contains eight cases, in only three of which lead was found. Of these three patients, one was a young lady in good circumstances, who was subject to peculiar attacks of petit mal, consisting in a sensation of nausea with little or no impairment of consciousness, and occasional attacks of temporary blindness of one eye. She was about twenty-five years of age, and had had the attacks for a number of years; no sign of lead cachexia was present, but lead was found twice in the urine, once in considerable quantity. At a third examination it was not found.

Of the second case I have no full notes. The patient was sixteen years old and had attacks of petit mal about once a week for three years: whether cachexia was present or not I do not know.

The third case seems to me of special interest. It is that of a student about twenty-six years of age, who had suffered during the past year from numerous attacks of petit mal, and one severe attack of outspoken epilepsy. There was no family predisposition to be discovered, and the patient could not remember ever to have had such seizures before, except that once, when about fifteen years old, while sitting at his desk reading or writing, his vision suddenly left him for a moment, as he thinks. The patient is decidedly pale, though this is in part natural; he looks rather feeble; there is slight tremor of the hands; he also did very well under treatment with potassic iodide, and bromide. The urine was examined three times for lead and twice it was found. I was inclined to make light of the connection between the lead and the epileptic symptoms until I found to my surprise, on asking the patient to extend the fingers and wrist to their full extent, to find that the three smaller fingers of both hands drooped considerably, those of the right hand more than those of the left, and that, on the electric examination of the muscles, the extensores communes digitorum of the right arm responded less easily to both galvanism and faradism than the corresponding muscles of the left arm. The interest of these cases centres on the inquiry which they suggest, whether lead can cause epileptic symptoms for any considerable length of time without signs of marked cachexia, or other serious phenomena of lead-poisoning. This condition, though certainly rare, seems to be occasionally met with.[24]

The epileptic attacks recorded as due to lead are usually severe and prostrating, but of course lighter attacks really due to lead may have been referred to some other cause. It seems to be certain that the children of parents with lead-poisoning suffer from convulsions, in which as a rule they die in infancy. That epileptic attacks of the type of petit mal may, however, be present for a long time without any serious cerebral symptom is well illustrated by the following case which I have recently observed.

It is that of a young woman twenty-seven years of age, employed in a shoe-shop in a country town, and drinking water which came, as is so common in country towns, through twenty feet of lead-pipe from a sunk well, the end of the pipe lying in the well. Her symptoms date back about three years. At this time her health began to fail, but she showed no more definite symptoms of lead-poisoning than frequent pains in various parts of the body, and in the abdomen, the latter, to be sure, so severe that she was thought by some of the physicians whom she saw, to have inflammation of the bowels. For two or three years she had, at short intervals, what she called "fainting spells," characterized by a loss of consciousness for two or three minutes, preceded by a sense of dizziness, but never attended by convulsions, and leaving her, after a few moments, in her normal condition. She also suffered a good deal with diffused headaches, and dizziness. After this state of things had continued for about two years, sometimes better and sometimes worse, she had a violent cerebral attack, with prolonged loss of consciousness, convulsions and amaurosis, lasting for nearly a week, and this was followed, after a time, by another similar, but less severe attack, and later by characteristic and severe palsy of lead, from which she recovered, only to be attacked by a similar paralysis of other muscles than those first affected. At the time of my examination there was an indication of blue line on the gums, incomplete extension of the fingers and wrist, and paralysis of the small muscles of the hands, with atrophy and reaction of degeneration.

Besides these groups of cases which I have reported, there are a number which do not fall under any single heading, with the recital of which I will not take the time of the association.

Looking back over all the groups, it may be pointed out: *first*, that the urines of persons known to be in perfect health, though their number is, to be sure, but few, were almost all free from lead; *second*, that in the cases of functional nervous disease, neurasthenia and epilepsy, the cases in which lead was found were in a decided minority; *third*, that in proportion as these nervous symptoms were associated with signs of organic disease, the proportion of cases in which lead was found became greater; *fourth*, that among the cases of organic disease, those in which lead was found with the greatest regularity were cases presenting symptoms of chronic diffused neuritis and chronic myelitis, especially of the motor tracts of the spinal cord; *fifth*, that among these cases, those which presented the least sign of cachexia, were those in which lead was not present; *sixth*, that the cases of progressive muscular atrophy showed no lead. Finally, I would suggest, as worthy of future study, the question whether lead may not cause epileptic symptoms of long continuance, without indicating its presence by other unequivocal signs.

In conclusion, I would call attention, as I have already done in a previous paper, to one occupation which has furnished me with several marked instances of lead-poisoning, and which, to my surprise, I cannot find set down among the dangerous employments from this point of view, and that is the manufacture of articles of rubber.[25]

[25] Lead has been found in the rubber ends of feeding-bottles, in Europe.

—A *cause célèbre* in English law and politics, that of a Miss Cass, arrested on Regent Street, London, has brought out the admission on the part of the Police authorities that no reputable female can be or is expected to be seen on that street after dark.

DISEASE IN THE MILK-CAN.

BY JULIUS S. CLARK, M.D., MELROSE, MASS.

IT is fairly well established that diphtheria is excited by some forms of bacteria yet to be individualized. However this may be, its contagiousness is undoubted, and equally certain it is, that its contagious material may be communicated directly by the patient or be transmitted to a distance in various material ways. The more usual channels for the spread of this disease are believed to be drainage and a polluted water-supply; and, equally certain, if less often determined, it may be from infected milk of healthy or diseased cows. The results of very many investigations in England, France and Germany, establish beyond cavil the fact that diphtheria does occur among domesticated animals, and especially the cow, from which its transmission has been traced again and again. How frequently it is spread from the milk of healthy cows, through contamination outside the cow, either by the water-supply to the milk, or from infected vessels, or from absorption of atmospheric contagium, is of vital consequence to all.

When we reflect upon the fact that milk is so sensitive to meteoric conditions and has such absorbent qualities, or affinity, so to speak, for atmospheric poisons, it seems strange that so much stress is put upon the responsibility of the animal, and so little attention or research is given to other possibilities. Whenever it is established, as it frequently and undoubtedly is, that scarlet fever, typhoid and diphtheria gain entrance to the family through the milk-can, it is hardly just or wise to condemn offhand, the friend of all and the foster-mother of many, the cow. In many of the towns in the vicinity of Boston, the local vendor of milk nominally furnished his patrons from the limited product of a few cows, which he ostentatiously parades, while his chief supply is from a general dealer, who on his part collects it of the small producer, more remote, from a house-to-house visitation. Thus it will be readily seen that the chances of infection are multiplied in the ratio of the greater number of original sources from whence the supply is derived.

If one of these many small tributaries that feed the general stream should be the habitation of some infectious disease, it will be seen that with a little carelessness, or with the ordinary care that is exercised in the handling of milk in the average home, it would be extremely liable to pollution. For, while the large producer of milk has separate and special apartments for the treatment of the same, the one-to-three-cow producer *safely* cares for his under his own living-roof, where it may be exposed to deleterious and unhealthy influences at all times. Some facts of interest bearing upon the propagation of diphtheria which prevailed epidemically in Melrose and Malden, during June, July and August of last year, and which was the direct and immediate outcome of an infected milk-supply, I will recite: Of the several cases occurring in my own practice, I failed to discover any of the classical grounds, or *loci causæ* obtaining, but incidental inquiry elicited the fact that each had a common milk-supply, and further investigation found it also true in the cases of other physicians. In Melrose, twenty-three cases occurred in twelve families. In one of these families the contagium was from immediate contact with contiguous neighbors, who were down with the disease.

We have, therefore, eleven distinct foci of infection widely separate, (two only being within the same square) being generally near a line from North to South, of two miles in extent, at intervals of one-eighth of a mile. At these eleven foci of infection, or original cases, a certain local vendor served seven with milk, another two, another one, and a fourth one, while these four obtained milk from two wholesale dealers, who, on their part collected it in a neighboring town and district where diphtheria was then prevailing, and *from families in which diphtheria then existed.* If these were coincident phenomena they attain to the marvelous, when we consider that, of probably thirty distributors of milk, this disease only followed in the trail of a certain supply and failed to appear on the routes of twenty or more who drew their supply elsewhere and none of whom peddled this particular milk.

In the interest of truth and to satisfy an awakened curiosity as to the extent of the mischief wrought by this milk-supply, I pursued it in its effects still further. Being furnished with a list of cases in Malden, for the same period, I continued my investigations with the following results: Number of cases reported, twenty-seven; number of families in which they occurred, eighteen; of these one was not to be found, and one claims to have contracted the disease from a neighbor in whom it existed and with whom they intermingled freely. Now, of the sixteen foci of infection to be accounted for, thirteen received the infected milk. Of the remaining three, who were served by two vendors who received their main supply from the cars, no history is obtainable, but it is quite possible that it came from this very infected locality. It is also more that possible that these vendors supplemented a deficiency occasionally, as they are wont, from a brother vendor, or, what is quite as possible, they procured it direct from the wagon of one of these distributors of the infected milk, who daily passed their doors to a market several miles beyond. Social relations may and do have influence in the spread of zymotic diseases; poverty, uncleanliness and the effluvia of animal putrefaction establish a general condition favorable to the genesis of miasmatic contagious diseases. At least, under such conditions their development is encouraged and extended and their virulence intensified — but how much more? Wherever diphtheria occurs we enthusiastically search for filthy surroundings, or defective drainage, as the primitive cause, and with our willing senses these can be had to our satisfaction; yet it is very doubtful if it is ever caused by sewer-gas, or that it is ever endemic in the sense that ague is. True, certain endemic conditions of a sanitary and atmospheric nature do supply in many instances the predisposing cause as applied to the individual and his surroundings.

This may be equally said of typhoid, yet who with our limited knowledge can assert, that the sole condition of parentage, the noxious agent, the real element-producing disease, are these essentially? Experience, observation and discoveries are reducing some heretofore probabilities to present possibilities.

Let us turn from the speculations of fancy to the logical teachings of absolute facts, as set forth. We have an epidemic of diphtheria extending over four miles in length, including fifty subjects of this disease in thirty families, or, twenty-eight distinct foci of infection. No facts can be had in one instance, thus leaving twenty-seven to be dealt with. Of these

twenty-seven foci of the disease twenty-four were supplied with milk coming direct from families in which the disease was known to exist, leaving three only wherein we fail to make out a case that would warrant a verdict for conviction. Of the fourteen deaths resulting from this epidemic, thirteen were in families using the milk known to be infected, and one in the family in which no history is had. We emphatically assert that thirteen deaths were the immediate result of an infection conveyed by milk-supply, *the mischief of preventable cause.*

We have local ordinances, Board of Health rules and statute laws, for the isolation of the sick, the non-intercourse of family members, the destruction and disinfection of clothing and habitations, wherein exist typhoid, scarlet fever, small-pox and diphtheria, but nothing to restrain what may be the most pernicious factor in the spread of these — milk.

NOTE.— The facts and data of the above, in the completest detail, are in possession of the State Board of Health.

RECENT PROGRESS IN OPHTHALMOLOGY.[1]

BY MYLES STANDISH, M.D.

PATHOLOGY OF OPTIC NEURITIS AND CHOKED DISC.

DEUTSCHMANN [4] writes that the so-called choked disc (stauungspapille) is from the beginning an inflammatory condition, a true neuro-retinitis. There is no evidence in favor of the supposition that it is caused by compression of the ocular end of the nerve; the anatomical facts are opposed to this assumption. Schultén, on the ground of original experiments on animals, has lately come forward as an advocate of the compression theory of Schmidt and Manz. He raises the intra-cranial pressure by means of injections of salt solution into the sub-dural and sub-arachnoid spaces. He produced thereby a narrowing of the arteries, and an overfilling of the veins in the retina; he assumed that these vascular changes were caused by compression of the nerve by fluid in its sheath, and that they truly represented the first stage of the condition known clinically as choked disc. In other experiments, Schultén raises the brain pressure by injections of oil, wax, or gelatine, and by the introduction of small india-rubber bags between the dura-mater and the skull. In this way, also, he obtained the vascular changes in the disc above described.

Deutschmann, accepting the above observations as accurate, denies that they support the compression theory of choked disc. The vascular changes produced were not proved to be the beginning of the morbid process in question, or to be produced by the compression of the ocular end of the nerve by an excess of fluid in its sheath. To settle the matter more positively, he determines to solve, by means of further experiment, the two following questions:

(1) What degree of hydrops of the optic nerve in animals is required to produce changes in the disc similar to those of choked disc in man?

(2) Are there any conditions under which a moderate and even transient hydrops of the nerve, such as is often found post-mortem in man, is associated with the occurrence of choked disc?

For the determination of the first question he injected directly into the nerve sheath. Dividing the superior rectus he laid bare and cut through the optic nerve in front of the optic foramen; then drawing forward the distal end, and taking especial care not to rupture the central vessels at their entrance into the nerve-trunk, he injected warm sterilized agar-agar solution, the advantage of which is, that, at the body temperature it remains of a soft semi-fluid consistence, and is only very slowly absorbed. A ligature being then applied to the nerve, the divided muscle was sutured and the wound closed; the whole with antiseptic precautions. Healing follows almost without trace of the operation. By filling the nerve-sheath very forcibly, he obtained ophthalmoscopic evidence of a total arrest of circulation in the retina, and a few hours later a swelling and turbidity of the papilla, much resembling the choked disc in man. Microscopic sections showed a well marked compression of the nerve close to the globe, a swelling and œdema of the papilla, but no trace of a true neuritis. When the injection was made less forcibly, however, though still sufficient to produce a more marked hydrops than is usually found in man, he obtained only a temporary diminution of the arteries, and an overfilling of the veins, and the microscopic examination, several days later, showed no trace of pathological change, either in the nerve or papilla. Deutschmann concludes that in animals a choking of the disc comparable with that which occurs in man, can only be produced by a pressure sufficient in amount to arrest the circulation. No one, he points out, has found a degree of hydrops in the human optic nerve approaching to this required amount; and, moreover, the frequent retention of good vision in such cases refutes the idea of an arrested circulation. In the next place, Deutschmann made injections of agar-agar into the cranial cavity in order to fill the nerve-sheath by means of pressure within the skull. By repeating the injection from time to time in the same animal, he established not merely a transient excess of pressure in the skull, but one which was renewed from time to time, and by the antisepsis he obtained the effects of pressure without the inflammatory complication. A well marked injection of the optic nerve-sheaths, are equal in degree to that which is found in the human subject under conditions of morbid pressure in the cranium, and lasting for several weeks, was produced. Dissection showed that the sheath was forcibly distended, but that papilla, the nerve-trunk, and its sheath, were absolutely free from any trace of inflammation. From these experiments Deutschmann concludes that an excess of intra-cranial pressure, with distention of the optic nerve-sheath, does not of itself suffice to produce the choked disc. Deutschmann therefore adopts the theory of Leber, that hydrops of the optic nerve is concerned in the production of choked disc in a manner other than that assumed in the compression theory, namely, that the products of new formations, (tuberculosis and intra-cranial tumors), mixes with inflammatory exudation and with cerebro-spinal fluid, are carried into the intervaginal space of the nerve, and at its bulbar extremity excite inflammation of its tissues. To test this view, he repeated his injection experiments, but used an infecting instead of an aseptic material. A few drops of tubercular pus were injected with antiseptic precautions into the sub-dural space. No reaction followed. Three weeks later the papilla began to redden, and the veins to become tortuous; swelling

[1] Concluded from page 79.
[4] Monograph, Jena, 1887, Ophthal. Review, April, 1887.

of the papilla followed, and then these changes either subside or became gradually intense, until typical appearance of papillitis were developed; the process reached its acme in the fifth week, and then gradually subsided, leaving the appearance of post-neuritic atrophy. The microscope showed widely-spread miliary tuberculosis of the meninges: the intra-cranial portion of the nerve normal, the orbital portion more or less altered, the sheath being more or less distended with exudation in the early stages, and occupied with tubercle deposits in the later; the nerve and the sheath being both inflamed. It was evident that the changes in the papilla were not pressure effects, for they were present before any considerable tubercle masses were formed in the sheath. The conclusion Deutschmann draws from these experiments is as follows: choked disc does not depend upon pressure, it is excited by an irritating fluid, which passes together with the cerebro-spinal fluid, from the cranial cavity, along the nerve-sheaths, and which is arrested at the bulbar end of the nerve, and there produces an infective action.

OPTIC NEURITIS IN HEAD INJURIES.

Drs. Edmunds and Lawford[5] report twenty-four cases of head injury, in which the condition of the optic nerves had been observed, either ophthalmoscopically or microscopically. The microscopic evidence of neuritis consists in a considerable increase of staining corpuscles in the sheath space and in the nerve.

The cases were divided into three groups:

(1) Cases which ended fatally, directly from the severity of the head injury; eleven cases, four of which had optic neuritis, were included in this group.

(2) Cases which ended fatally, indirectly from complications; the group comprised four cases, two of which had optic neuritis.

(3) Cases which recovered; eight cases, six of which had optic neuritis, were included in this group. The optic neuritis was attributed to the spread of inflammation from the seat of the injury to the optic nerves; this might take place either along nerve tissue or by the meninges. The authors adopted the latter view, because: (1) while in some of the cases in which there was optic neuritis, basal meningitis was found; it never occurred in those cases in which optic neuritis was absent. (2) Those cases in which the base of the skull or brain was injured generally had optic neuritis, while those in which the injury was confined to the convexity of the brain, such as punctured wounds, had not. (3) In some cases of neuritis, transverse sections of the optic nerves showed the inflammation most marked at the periphery of the nerves and in the sheath space. The same authors, in reply to Deutschmann's article, say,[6] that if his theory be correct, he should be able to show that if the animals he killed in the first few hours or days after inoculation no optic neuritis is present; that at a later stage inflammation confined to the bulbar end of the nerve is found, and that later still the whole length of the nerve is involved. But that he does not say this, and that his statement is that the intra-cranial portion of the optic nerve was found normal, and that the intra-orbital parts altered, the inflammation being more marked near the eye than posteriorly; but this is not conclusive, for the normality of the intra-cranial portion of the nerves would not exclude the possibility of the inflammation found in the distal portion, having descended by the meninges of the nerve, which he admits were found inflamed. The inflammation of the sheath space appearing more intense near the eye, may be due to the sheath being looser at the anterior part of the nerve, and consequently allowing more free exudation. They have themselves examined some forty cases, and in every case in which papillitis was seen during life there were inflammatory changes in the optic nerves in their entirety. In a few instances the inflammation was confined to the proximal part of the nerve, and in these cases the papilla, both to the ophthalmoscope and to the microscope, showed no changes, death having occurred before the inflammation had time to travel down the nerves as far as the papillæ. In two specimens recently prepared by longitudinal section, inflammatory changes can be traced from the optic foramen to the disc.

CHOKED DISC (STAUUNGSPAPILLE) IN CEREBRAL HÆMORRHAGE.

Remak,[7] in an argumentative article upon the causation of choked disc in conjunction with cerebral hæmorrhage, gives five cases, the last observed by himself in which cerebral hæmorrhage was caused either by the rupture of an aneurism or a bloodvessel in the brain, and was accompanied by choked disc. The aneurism was generally situated at the bifurcation of the internal carotid, and the hæmorrhage was of a large amount. In two of the cases the nerves were very carefully examined. The conclusions drawn are, that the phenomenon of choked disc in these cases is due to the compression of the central vessels of the optic nerve, in their course through the intervaginal space, through the pressure of blood clotted there, thereby causing an arterial anæmia and venous congestion of the papilla and retina. Our author considers another cause of choked disc to be the interruption of the lymph stream flowing from the eye through the sheath of the optic nerve into the sub-dural space of the cranium. This condition of the lymph circulation as occurring with cerebral hæmorrhage, was shown by the œdema of the retina, the papilla, and the distention of the intervaginal space near the bulb by lymph.

Clinical Memoranda.

A CASE OF BROW PRESENTATION CONVERTED INTO FACE; HIGH FORCEPS.[1]

BY EDWARD REYNOLDS, M.D.

M. S., married, native of England, II para. Labor began at 10 A. M., January 11th, but she did not send for medical assistance till 6.30 P. M., though the pains are said to have been severe all day. I was sent for first at 8.30 P. M., when the os was of the size of a dollar. The brow presented, M. R. P., and was so far extended that the mouth was within the os. The fœtal heart was strong and regular, the caput large and firm. Almost all the liquor amnii had drained away. The pelvis was roomy, but a mass of about

[1] Read, by invitation, before the Obstetrical Society of Boston, May 14, 1887.

the size of an orange could be felt by external palpation in the right wall of the uterus and just above the pelvic brim; this was not reached per vaginam.

It was evident that the presence of a fibroid in the lower uterine segment and on the right side, had thrown the occiput of a head presentation O. L. A. into the opposite (left) iliac fossa, and that its detention there had produced extension so soon as the upward retraction of the fibroid permitted the descent of the chin.

Feeling that the case was likely to prove difficult, I sent for Dr. C. M. Green in consultation. On his arrival the patient was etherized and a more thorough examination made. The fibroid was entirely above the head, and the adaptation between head and pelvis was easy.

It was decided to extend the head and make a tentative application of the forceps, and failing with them to have recourse to version.

The head was easily extended to a face, M. R. P., no rotation was attempted for fear of complicating the version, should that be necessary, and forceps were applied by Dr. Green, with the tips reversed, in the hope of promoting the fullest possible extension and consequent rotation. A few strong tractions produced no effect, the forceps were removed and version determined on.

As a preliminary, I attempted to flex the head, fearing that the prominent occiput of a face presentation might put too great a strain on the probably thin lower segment, during the passage of the hand; but finding that though the head was easily returned to its original position, any further flexion was impossible, I re-extended it and cautiously passed the hand upward in search of the obstacle, and was surprised to find that the neck of the child was firmly grasped by a spasmodic contraction ring.

All idea of version was now abandoned, the chin was easily rotated to the front (M. R. A.) by the hand, and the forceps reapplied by Dr. Green, who succeeded in delivering, after great difficulty, an eight pound female child. It was somewhat asphyxiated but was resuscitated without much difficulty.

Mother and child did well, and an examination two weeks later demonstrated the presence of an intramural fibroid, of about the size of an English walnut and situated just at the junction of the body and cervix. The mechanism of the case is to me most interesting; that a fibroid in the lower uterine segment should have jammed the occiput into the opposite iliac fossa, and then by its retraction have permitted extension to take place; that this extension should have delayed a normal head in a roomy pelvis until the exhausted uterus had closed down upon the neck in a constriction ring; that forceps to the face should have failed, when the chin was posterior, but succeeded after manual rotation of the chin to the front, are all points which are certainly full of practical interest.

A CASE OF DOUBLE DISLOCATION OF THE HIP.

BY O. J. PFEIFFER, M.D., DENVER, COL., *Chief Surgeon Union Pacific Railway Company.*

On April 3, 1885, Anna Lindstrom, aged eight years, a deaf-mute, while running along a narrow-gauge railroad track was overtaken, knocked down and run over by a switch engine.

When called to see the case, the legs seemed to be all tangled up, and as the child could bear no manipulation and could answer no questions, Dr. L. E. Lemen having been called in consultation, ether was administered by an assistant and the case was examined.

The left leg, perfectly straight, was rotated inwards so that the left foot lay flat upon its inner side; the left inner condyle of the knee pointed vertically downwards toward the plane of the bed and was resting upon it; the head of the left femur was felt directly outside of the tuberosity of the ischium.

On flexing the left leg to a right angle with the thigh, resting the leg upon my left forearm and moving the left knee upwards in a long vertical arc the head of the femur could be felt to describe a short arc outside and alongside of the tuberosity of the ischium.

The right hip was dislocated upon the dorsum and the right foot rotated inwards and drawn up lay upon and obliquely over the left instep.

The seventh, eighth and ninth ribs were broken at about the angle, and the left forehead and left side of the face were scratched and abraded, and filled with sand.

I remarked that, as dislocated hips were abundant, we would take one apiece, the ischiatic dislocation falling to my lot.

Both dislocations were reduced by Dr. Bigelow's method of manipulation, the chest after a deep inspiration was bound with a swathe and the face wounds cleaned and dressed. A towel was placed between the knees and they were tied together; the patient was placed upon her back, ice bags were applied to the hips, and in three weeks the child was up and about.

The child had been struck by the pushbar of the engine, knocked down head foremost, and in being passed over by the engine had been so gyrated that though she had fallen to the ground head foremost she was picked up with her head to the rear.

The distance between the rails was three feet, and the distance between the lowest part of the narrow-guage engine and the road-bed was seven inches.

It is remarkable that the child, having passed through so small a space, neither of the femora had been broken.

Reports of Societies.

AMERICAN OTOLOGICAL SOCIETY.[1]

Twentieth Annual Meeting.

Dr. Roosa also reported the history of a case of

suppuration of the tympanum occurring in a patient with bright's disease.

The patient, a woman aged forty-two years, was seen April 11, 1887. There was intense pain referred to the left ear which had existed since the day before. The hearing was much impaired as the result of a chronic non-suppurative inflammation of the middle ear. The bone conduction was better than the aerial. There was a watery discharge from the left auditory canal. Examination of the urine revealed the presence of Bright's disease, and the patient died some days later from œdema of the lungs. The point which the author made was that although this patient com-

[1] Concluded from page 90.

plained a good deal of the mastoid process, it was determined there was no lesion requiring operation, because of the absence of the characteristic symptom of tenderness at the apex. The case was regarded as one of tympanic trouble. The post mortem proved that there was no trouble with the mastoid, but acute suppuration of the tympanum occurring in a patient with chronic non-suppurative inflammation. The patient died from the Bright's disease.

DR. W. H. CARMALT, of New Haven. The author speaks of tenderness of the mastoid as though it were an almost infallible sign of suppuration in the mastoid cells. I would ask if we should expect to find this sign always?

DR. ROOSA. I think that this is a very strong test, although by no means infallible.

DR. EMIL GRUENING, of New York. I have this winter seen a number of cases of abscess. In two months I saw seven cases. In children, I open the abscess and invariably open the mastoid cells. I do this especially where the abscess has been preceded by otitis media purulenta. In four of the seven cases the mastoid cells were filled with pus. In this way thorough drainage was established, and all the patients recovered. I saw three cases of otitis media purulenta treated by insufflation of powder, leading to retention of secretions and death. All died of meningitis.

DR. B. E. FRYER, of Kansas City. I would ask whether the abscess and the affection of the ear were of the same duration?

DR. ROOSA. I think that the cerebral abscess was of long duration, months, possibly years. The abscess was undoubtedly induced by the tympanic disease.

DR. LUCIEN HOWE, of Buffalo. This case calls to mind one which I had in a child, where there was a history of recurring attacks of ear trouble with discharge. It was stated that good results had been obtained by the use of alum and boric acid. This was continued and the patient began to develop the typical signs of mastoid trouble. I etherized the child and removed the accumulation in the outer ear; all the symptoms then subsided.

DR. W. H. CARMALT, of New Haven. The fact that the cerebral abscess was surrounded by a thick membrane does not prove that it was of long duration. In a recent case of cerebral abscess resulting from an injury over the parietal bone, I attempted to reach the abscess by trephining, and passed my knife two and one-half inches in the direction where I supposed the abscess to be, but got no pus. The man died and I found an abscess in about the position I had passed the knife, but the wall was so thick that the pressure of the knife had squeezed the pus into the lateral ventricles, and death had been the result. In this case the operation was performed within two months of the original injury.

A paper entitled

DESQUAMATIVE INFLAMMATION OF THE MIDDLE EAR, WITH REMARKS,

by DR. O. D. POMEROY, of New York, was read by title and referred to the publication committee.

AN EFFICIENT POWDER BLOWER, WITH REMARKS ON THE USE OF POWDER IN THE TREATMENT OF DISEASES OF THE EAR,

by DR. E. E. HOLT, of Portland.

The powder blower consists of six or eight inches of small glass tubing to which is attached about fifteen inches of rubber tubing. The glass tube is plunged into the powder until a sufficient amount is introduced into it. The powder is gently drawn into the proximal end of the glass tube. The distal extremity is then placed in the speculum and the powder blown into the ear. By drawing the powder from the distal end before blowing it, it is carried *en masse* to the desired point and applied evenly to all parts. The instrument can be used with great facility.

After trying various powders, boric acid has been found the most efficient in the largest number of cases. One of the first cases in which the author had used this powder was one in which treatment for over two years had failed to cure a suppurative otitis media. Upon the application of the powdered boric acid, the discharge ceased and has not returned in a period of five years. Cleanliness, before using the powder, is essential. A comparison of cases of chronic suppurative otitis media treated with boric acid with those treated without this agent, led to the conclusion that while the discharge from the ear ceases much earlier when the powder is used, yet perforations in the drum head, heal less frequently.

DR. SAMUEL THEOBALD, of Baltimore, exhibited a powder blower similar to that of Dr. Holt, with the exception that the glass tube was substituted by a piece of goose-quill, and that the rubber tube was furnished with a mouth-piece consisting of a quill. The powder is introduced into the quill, and by shaking brought to the proximal extremity of the tube, the object being that it shall be thrown into the ear in the form of a cloud.

DR. W. W. SEELY, of Cincinnati. I have never seen any fit from blowing powders into the ear. I have only seen good results where the powder is packed into the canal. I, however, now rarely use the powder in any way. In these cases of suppuration there are three points to be observed, the eustachian tube should be kept open, the naso-pharynx should be treated as in any other case of inflammation of the middle ear, and the ear should be kept clean by the use of cotton probes.

DR. D. B. ST. JOHN ROOSA, of New York. I find the syringe the best means of cleaning the ear. I use powders with great circumspection. They are inferior to other methods of treatment.

DR. B. ALEXANDER RANDALL, of Philadelphia. In treating a number of cases of purulent discharge which had continued from five to fifteen years and in which the discharge had been pretty continuous and fetid. I have cleansed the canal and used boric acid, at first blowing it in lightly and finally filling the canal pretty full without packing. Within a few days the powder is dissolved and the discharge is usually diminished in quantity and the odor is lost. In eight out of every ten cases, that has been my experience. I have never seen any bad results.

DR. H. KNAPP, of New York. In acute cases of otorrhœa I use boracic acid as an antiseptic and cleansing powder. The patient is directed to cleanse the ear with the syringe three times a day. The powder is then introduced by means of a spoon until the canal is loosely filled. If the powder becomes moist the patient is directed to syringe the ear and renew the application. The majority of acute cases do not require any other treatment. In chronic cases I remove any

polypoid growths or any carious bone that may be present, and then use alcohol in fifty or sixty per cent. strength or absolute with sulpho-carbolate of zinc, and change that with nitrate of silver. I continue this treatment until the ear is dry and there is no discharge, and direct the patient to do nothing beyond using a light cotton plug to filter the air. I do nothing to the perforations. In one case I make an exception, and that is, when a perforation of moderate size has perfectly clear edges and remains in the same condition for weeks or months. Here I paste a small piece of sized paper over the perforation. In many cases the hearing is improved, and it seems to stimulate the healing of the perforation.

Dr. C. R. Agnew, of New York. In using fluid applications in the treatment of these cases I have employed a procedure which may be new to some of the members. After cleaning the ear in which I want to diffuse a fluid application as much as possible, I turn that ear uppermost and fill the external canal with the solution. Then I insert the nozzle of my Politzer apparatus into the external canal and make pressure, diffusing the liquid to all parts of the ear and making it appear in some cases in the pharynx. This sometimes may be of value.

Dr. Samuel Theobald. I think that both powders and solutions may be used with advantage. I have never seen any direct harm follow the use of boracic acid. In cases of suppuration with a small or moderate sized perforation, I have seen it dry up the discharge and leave the perforation larger than before its use. In such cases, I prefer solutions. In acute cases my practice is to always use solutions. I have used a fifteen grain solution with satisfaction. Where the drum membrane is practically gone, with a granular condition of the mucous membrane, the use of boracic acid powder is indicated. I have never found it necessary to pack the canal. One puff of the powder-blower fills the canal sufficiently full.

AFTERNOON SESSION.

The interesting discussion on the use of powders in the treatment of inflammation of the ear was continued.

Dr. H. Knapp, of New York. In acute suppurative otitis, which is certainly of bacterial origin, I use boric acid largely, on account of its drying properties. Suppuration, fermentation and decomposition do not take place where a part is kept dry. The ear is unfavorable for thorough drainage. As soon as the boric acid becomes moist, I have it removed. For acute cases, I know nothing better than this method of treatment.

Dr. Emil Gruening, of New York. I should like to make a few remarks with reference to three cases which I have already mentioned. In these cases I attributed the fatal result to the use of powder, which was boracic acid. The first case, that of a girl nine years of age, had otitis as a result of the use of the nasal douche. She was advised to use powders. In a few days she began to suffer with headache, dizziness, and intense tenderness on one side of the head, and slight puffiness in the region of the mastoid. I saw the patient after she had become comatose. I found the tympanic membrane bulging. It was injected. There was a slight tit-like projection, and in this there was an opening filled with powder. The pus which formed in the middle ear escaped through the eustachian tube. I made an opening in the membrane and cleaned it out carefully, and advised the family physician to open the mastoid. He did so, and found the mastoid cells filled with pus. The patient recovered consciousness, but died the next day from heart failure. The second case was that of a lady seventy years of age, who had otitis media with perforation. A powder was applied by a general physician, and a few hours later, she began to suffer with intense headache. Symptoms of meningitis appeared, and I was called in. I found a small opening in the membrane occluded with powder. I made an opening, but the patient died of meningitis. The third case was that of a child with long standing otitis media, and destruction of both membranes. This is the only case in which the powder had been packed. After the ears had been packed the child had repeated chills. I was called in, and removed the plugs, which were hard concrete masses and were taken away with difficulty. In spite of the removal of the powder the child died with all the symptoms of pyæmia.

Dr. D. B. St. John Roosa, of New York. I think that in a large percentage of cases acute inflammation of the middle ear is a self-limited affection. I try to secure cleanliness, and then dry the parts. I do not use dryness as a means of destroying of the germs or preventing them from acting, for I do not believe in the germ theory of disease. I think that germs are the products and not the causes of disease; I think that they retard recovery and therefore should be removed. In a large proportion of the acute cases the only treatment required is irrigation with warm water, pro re nata, and drying afterwards. I believe that the pus has a chemical quality apart from the presence of germs, which renders it corrosive. I therefore try to keep the parts as free from pus as possible.

Dr. Samuel Sexton, of New York. I think that it would help us in this discussion to consider the kind of cases in which boric acid is useful. Where there is a catarrhal inflammation of the atrium there is generally a profuse discharge which renders it difficult to apply the powder. In the cases referred to by Dr. Gruening, where there is a nipple-like formation, there is little discharge from the atrium. In these cases I make an early and free opening, and in this way I have avoided many of the consequences which are apt to follow in these cases. I make this opening with a stout tenotome. An opening is made through the membrana flaccida into the attic and through the integument of the upper wall, which usually becomes tumefied.

Dr. Samuel Theobald, of Baltimore. I would enter my protest against the view that the good effects of boric acid are due to its drying qualities. Some of my most brilliant results have been with the solution of boric acid. I have had cases in which the discharge has stopped after a single application of a saturated solution of boric acid.

Dr. J. A. Lippincott, of Pittsburg. I count boric acid a most valuable agent, and would not care to relinquish its use. There are, however, certain cases in which as a result of idiosyncracy on the part of the patient, the powder acts as an irritant. In the cases reported by Dr. Gruening, the fatal results are to be attributed to its improper use. It seems to me that the dangers of boric acid can be avoided by applying it in the form of a loose powder.

AN EXAMINATION OF FIFTEEN DEAF MUTES BY MEANS OF J. A. MALONEY'S OTOPHONE,

by CHARLES H. BURNETT, M.D., of Philadelphia.

The cases examined were pupils in the Pennsylvania Institution for the Deaf and Dumb, Philadelphia, and were between the ages of twelve and twenty-one years of age. The cases were divided into three classes: (1) congenital cases; (2) those losing their hearing between the ages of one and five years; (3) cases of profound hardness of hearing, but who still hear a little and can talk so-called semi-mutes.

The method of procedure was as follows: five vowels were written and pointed out at the time of their repetition three times in succession through the otophone by Mr. Maloney. The pupil was then told to indicate which vowel was spoken when Mr. Maloney made another repetition, care being taken to mix about in the tests. The words Philadelphia, Mississippi, Burlington, Missouri, boy, baby, papa and mamma were also used as tests, as well as the consonant B.

Hearing was excited in every instance; but fourteen of the fifteen cases gave ample evidence of hearing by their successful indications with the pointer as the different tests were repeated in their ears. It was noted that the results were not as good with the acquired cases as in the so-called congenital cases of deafness. This may be due to the fact that the process productive of the acquired form is more violent, involving the internal ear, as in spotted fever, than in congenital cases which generally give evidence of being simply catarrhal in their origin, and affect the middle ear but not the internal auditory organ. In the case of semi-mutes the results were especially satisfactory, as they heard nearly everything said to them, and returned intelligent answers to the questions. In such cases both the remaining hearing and the articulation could in all probability be improved by the systematic employment of such an instrument as the otophone as a means of instruction, the best results being obtainable where the instruction is begun early in life.

A paper with the same title was presented by Dr. F. B. Loring, of Washington. In the absence of the author, the paper was read by title.

DISCUSSION.

DR. WM. W. SEELY, of Cincinnati. I would ask whether the use of this instrument is recommended simply as a help to hearing, or as a therapeutic measure?

DR. C. H. BURNETT, of Philadelphia. The instrument seems to be an immediate help, and is also a valuable therapeutic measure. In the case of an extremely deaf person who was unable to hear a loud voice when the words were spoken close to the ear, and when, with an ordinary ear trumpet, could hear slightly, with this instrument he could hear fairly well from the first. After exercising for fifteen minutes, he was able to hear with closed eyes the unaided voice, the words being spoken a foot from the ear.

DRS. H. L. MORSE, of Boston, and B. ALEXANDER RANDALL presented a series of

PHOTOGRAPHIC ILLUSTRATIONS OF THE ANATOMY OF THE HUMAN EAR.

EXCISION OF THE OSSICLES OF THE DRUM OF THE EAR FOR CHRONIC PURULENT INFLAMMATION OF THE MIDDLE EAR TRACT,

by SAMUEL SEXTON, M.D., of New York.

Since bringing this subject to the attention of the Society, one year ago, the writer has continued the practice with satisfactory results, and presented some further observations based upon the records of nineteen operations. Of these nineteen cases, thirteen were females and six were males. Seven cases were between five and twelve years of age, eight were between thirteen and twenty years of age, and four were between twenty-three and forty years of age. The left ear was affected in eleven cases, the right in eight. In two cases both ears were the seat of suppurative inflammation, and in one there had been a mastoid abscess. In a majority of the cases there had been a history of recurrent aural catarrh for a long time attended with pain in the ear. There was much deafness and distressing acoustic phenomena, as autophonia and the like. The discharge was usually offensive. The general health of most of the patients was fair.

In all cases the drum-head was greatly impaired, the membrana vibrans being usually almost entirely gone; in most of the cases the membrana flaccida alone remained, perhaps with some portion of the membranum vibrans attached. Where any of the latter remained, it was liable to be found connected by bands with the inner wall of the tympanum. Sometimes a sinus of greater or less size opened through these diseased structures into the attic. The membrana flaccida together with the membranous and ligamentous attachment of the ossicles generally held the latter in place, even after the most extensive suppuration had long existed. Under these circumstances, drainage was extremely likely to be interfered with. The manubrium and cicatrical structures depending from the auditory plate were frequently found adherent to the inner wall of the tympanum, which the attic and antrum were lined with much thickened mucous membrane.

Some portion of the middle-ear tract was found to present more or less carious bony surface. In some instances, the ossicles themselves were carious or anchylosed. In several of the cases, the malleus handle was adherent to the inner wall of the drum. In some only a necrosed stump remained. In some the malleus and incus were adherent to each other. The incus was less liable to caries. The tapes cannot be so well examined as the other bones, since it is never removed. In some of the cases the operation was not resorted to until months or years after ordinary methods of treatment had been resorted to without success.

Without going into all the details of the operation, the author said that experience had shown that it may be performed much more rapidly than was at first supposed. The first operations required an hour, the later ones not more than fifteen minutes. To the protracted operation he attributed some disagreeable symptoms, such as nausea, which had not been presented by the later cases.

The remaining fragments of the drum-head are everywhere detached from the tympanic ring with a slender trowel-shaped knife. The malleus is then freed from its attachments, including the tensor tympani muscle by one or more sweeps of the knife. After all blood is removed the long process of the incus is separated from the stapes, if it be connected with that bone. The malleus handle is separated from the inner wall of the canal if it had been attached. The malleus handle is seized with stout forceps as high as possible and gradually detached and brought away. The re-

moval of the incus is more difficult, since its long process is liable to be swept from view. With a little patience, however, the bone may be soon found, and its removal is then a simple matter. When lying in the attic the scraper may be of service in bringing it down. In most instances he no longer divides the chorda tympani. In some cases where the ossicles were very adherent, considerable force was necessary to detach them, and in one instance this was impossible.

After the operation, the drum should be carefully dried with cotton and ten drops of a four per cent. solution of cocaine may be instilled. This is usually unnecessary. Usually, very little or no reaction follows the operation. In females it is important to defer operation until a little time after the menstrual period.

In the nineteen cases both malleus and incus were removed in ten. In one the body of the incus alone was removed. In six cases the malleus only was excised.

When possible, it is well to clear the drum of granulation tissue by treatment before the operation, since less hæmorrhage will then be encountered. The duration of treatment after the operation was, in five cases, one month; two, two months; in two, three months; in one six months, and of the other nine cases, three cases unimproved, one failed to continue treatment, and five are yet under observation. Nine cases progressed steadily to a complete cure; six were much improved; three were unimproved, and one failed to continue treatment. Many of these were dispensary patients under bad physical conditions. A marked improvement in hearing occurred in nearly all cases. In the cases noted as cured, the hearing was improved from 75 to 100 per cent., as far as testing with voice was concerned.

This marked improvement in hearing was unexpected, and gave rise to the conjecture that we may recommend the operation for deafness alone in many cases where the drum is obstructed by the results of chronic purulent inflammation, although all discharge may have ceased.

It might be expected that the taste might be affected by injury to the chorda tympani nerve. In a few this was the case for a short time, recovery, however, always took place. Reproduction of the drum-head never took place. Among the results of the operation may be mentioned the prevention of recurrent accumulations of purulent matter in the attic and antrum. The general health was nearly always improved. In two phthisical cases the cough was lessened in one and ceased in the other, while both gained much in weight. In children the effect on health was most marked.

The operation is performed with the patient upon the back and under ether narcosis. The electric light is almost essential. Magnifying lenses introduced into the speculum are of service. The after treatment consists in keeping down granulation tissue and aiding in the transformation of the mucous lesions into a dermoid condition. A meddlesome plan of treatment is undesirable. Where a large secreting tract exists a cure is sometimes almost impracticable. Alcohol has not been found useful in treating granulation tissue. Salicylic acid and boric acid have done good in a few cases. The peroxide of hydrogen has its use in certain cases. The persistence of discharge after operation may be expected in catarrhal and run-down subjects, especially where caries of the bone exists.

The specimens removed in these nineteen cases were presented.

DISCUSSION.

Dr. C. H. Burnett, of Philadelphia. I had the pleasure of seeing seven cases that had been operated on by Dr. Sexton. One was of fifteen months standing. There was no evidence of reproduction of the membrane. In the longer cases, there was no discharge. In the cases more recently operated on, there was still some discharge. In five of the seven cases, according to the statements of the patients, the hearing had been greatly improved.

EVENING SESSION.

A CASE OF RAPID AND ALMOST TOTAL LOSS OF HEARING IN A CHILD SEVEN YEARS OF AGE; INHERITED SYPHILIS APPARENTLY THE CAUSE; MARKED IMPROVEMENT FOLLOWING THE USE OF IODIDE OF POTASSIUM,

by Dr. A. H. Buck, of New York, was read by title.

Dr. Samuel Theobald, of Baltimore, reported a case of

SYPHILITIC DISEASE OF THE LABYRINTH,

exhibiting remarkable variations in the degree of deafness.

The patient was a man about thirty-four years of age, the subject of inherited syphilis. In one ear the deafness was nearly complete, and in this ear there was but little variation. In the other ear frequent and sudden relapses occurred, after the hearing on several occasions had been brought up almost to the normal standard. Within twenty-four hours the hearing would fall from the ability to distinguish words in a whisper at twenty inches, to a degree of deafness which would require the same words to be spoken in a loud voice. Iodide of potassium was given with but little effect, but decided benefit resulted from the administration of bichloride of mercury in combination with muriate of ammonia.

EXECUTIVE SESSION.

The following were elected to membership: Drs. J. C. Lundy, of Detroit; Wm. H. Hotchkiss, of New Haven; S. D. Risley, of Philadelphia, and David De Beck, of Cincinnati.

Officers for ensuing year: President, Dr. J. S. Prout, of Brooklyn; vice-president, Dr. George C. Harlan, of Philadelphia; secretary and treasurer, Dr. J. J. B. Vermyne, of New Bedford, Mass.; representatives to executive committee of Congress of American Physicians and Surgeons, Dr. C. R. Agnew, of New York, alternate Dr. Wm. H. Carmalt, of New Haven.

The next meeting of the Society will be at the Pequot House, New London, Conn., Tuesday, July 19, 1888.

— "Buck" Taylor, the "King of the Cowboys" who sustained a compound fracture of the thigh while in the discharge of his professional duties in connection with the Wild West Show, while a patient at the West London Hospital, had to be moved from the general ward to a private room from "the extraordinary and lavish concourse of ladies" who visited him.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

TWENTY-THIRD ANNUAL MEETING.

THE twenty-third annual meeting of the American Ophthalmological Society was held at the Pequot House, New London, Conn., on Wednesday and Thursday, July 20 and 21, 1887.

WEDNESDAY.— FIRST DAY.— MORNING SESSION.

The meeting was called to order by the President, DR. WILLIAM F. NORRIS, of Philadelphia.

Under the head of unfinished business the following were elected to membership: Drs. J. B. Emerson, New York; H. F. Hansell, Philadelphia; J. O. Taussley, New York; M. Hayward Post, St. Louis, and Edmund C. Rivers, Denver, Col.

A memoir of Dr. Ezra Dyer, of Newport, R. I., one of the founders of the Society, was read by Dr. Hasket Derby, of Boston, and referred to the publication committee. The death of Dr. William S. Little, of Philadelphia, was also reported.

The first paper read was entitled

REPORT OF THIRTY-SIX CASES OF SIMPLE EXTRACTION OF CATARACT WITHOUT IRIDECTOMY,

by DR. C. S. BULL, of New York.

Of these thirty-six cases, twenty were males and sixteen females. In twenty-four the cataracts were hard and senile, in eleven they were traumatic and soft semi-soft, and in one case, it was of secondary origin. There were corneal maculæ in three cases; tremulous iris, in seven; old choroiditis in five; and irido-choroiditis in one. Careful antiseptic precautions were adopted in all the operations.

The operation was done with the patient lying in the bed he was to occupy after operation. The speculum was employed in every case. The knife was long and narrow, narrower than that of von Graefe. It was quickly passed across the anterior chamber, the flap measuring about two-fifths of the corneal circumference. Prolapse of the iris did not usually occur, but if it did, it was allowed to remain until the extrusion of the lens. The capsule was then opened by a quadrilateral incision, and by pressure the lens was caused to pass out of the corneal wound. If reduction of the iris did not occur spontaneously, it was reduced with a spatula. All soft lens matter was washed out with the antiseptic solution and one drop of a solution of eserine instilled of the strength of one grain to the ounce of a saturated solution of boracic acid. The lids are then closed and an antiseptic dressing applied. If the eye did well the bandage was not removed for two days, but the eserine solution was instilled twice daily under the bandage. At the end of two days the bandage was removed and the eye washed. The lids were not opened for four days unless there was some indication for it. If at the end of this time, the appearance was favorable, eserine was reinstilled, and the bandage applied for another day when it was removed altogether.

The healing process was usually favorable; there was no suppuration in any case. There were six cases of plastic iritis of a mild type and two cases of irido-cyclitis. In the first thirty cases there was no incarceration of the iris. In the last six cases in the treatment of which the same care was manifested, incarceration occurred in every instance. The average duration of the treatment was a little more than twenty days. A secondary operation, usually a needling or a laceration of the posterior capsule was required in twelve cases. Prolapse of the vitreous occurred in four cases, and dislocation of the lens downward in two cases. Eserine was not used after the healing of the cornea. The degree of acuteness of vision obtained was as follows: $\frac{20}{XXX}$ in two cases; $\frac{20}{XL}$ in eight cases; $\frac{20}{L}$ in eight cases; $\frac{20}{LXX}$ in ten cases; $\frac{20}{C}$ in five cases, and $\frac{20}{CC}$ in two cases. In one case the eye was blind before operation, as the result of irido cyclitis. The technique of the operation is more difficult than where iridectomy is performed. The knife must be passed rapidly in order to prevent injury to the iris. The extraction of the lens is more difficult, and the danger of prolapse of the vitreous is more imminent.

DISCUSSION.

DR. H. KNAPP, of New York. During the past year I have performed Pana's operation sixty-eight times. Following the operation there was mild iritis in three cases; severe iritis with closure of the pupil in one case; protrusion of the iris in three cases; incarceration of the iris without protrusion in two cases; capsulo-iritis in one case, and suppuration in one case. This was secondary to an old disease of the eye. In twenty-seven cases a secondary operation was performed. In one case I performed the operation in a man much addicted to drink. The operation was successful, but there was slight wrinkling of the capsule. In the fourth week I made a simple division of the capsule. For twenty-four hours there was not a trace of reaction. The following night he had an attack of acute iritis with dysentery, and the urine was loaded with albumen. The next day there was circumcorneal injection, and the ball was very hard. Eserine reduced the tension but did not contract the pupil. On the third day the ball was as hard as it is in any case of acute glaucoma. I then made an iridectomy and the patient recovered.

REPORT ON A SERIES OF ONE THOUSAND SUCCESSIVE CASES OF EXTRACTION OF CATARACT WITH IRIDECTOMY,

by DR. H. KNAPP, of New York.

These one thousand cases were operated on during the years from 1866 to 1886. A tabular statement was given, showing the results obtained in each series. V = $\frac{20}{CC}$ to $\frac{20}{XX}$ was considered a good result; V = $\frac{21}{CC}$ to $\frac{1}{CC}$, was considered a moderate result, and where V = less than $\frac{1}{CC}$, the case was regarded as a failure.

In the first series of cases, the method of extraction was by a very peripheric section more curved than linear, with the following results: good 70%; moderate 22%; failures 8%. Of the failures 3% were from suppuration. In the second series, a peripheric linear section was employed. Results, good 86%; moderate 12%; failures 2%, all from suppuration. In the third series, linear section was employed. Results, good 86%; moderate 9%, and failures 5%, 3% of which were due to suppuration. The fourth and fifth series were performed by peripheric linear section with removal of the anterior capsule. Results, good 82%; moderate 7.5%, and failures 11.5%, of which 8.5% were due to suppuration. In the sixth series in which peripheric linear incision with peripheric capsulotomy was performed, the results were, good

89%; moderate 1%, and failures 10%, of which 8% were due to suppuration. The seventh series was operated on by the same method, only the section was less peripheral. Results, good 88%; moderate 7%, and failures 5%, of which 2% were due to suppuration. The eighth series was operated on by circular marginal section, with peripheric capsulotomy and with antiseptic precautions. Results, good 90%; moderate 8%, and failures 2%, of which 1% was due to suppuration. The ninth and tenth series of cases were operated on in the same way with the following results; good 90.5%; moderate 5.5%; failures 4%, of which 3% were due to suppuration. The results obtained, taking the one thousand cases as a whole, were, good 85.2%; moderate 9%; failures 5.93%, of which 3.8% were due to suppuration.

DOES SUNSTROKE AFFECT THE SIGHT PERMANENTLY?

by DR. J. A. SPALDING, of Portland.

The author introduced the question of the permanent effects of insolation (or sunstroke) upon vision. So many pension claimants were now coming forward, asserting that they suffered from sunstroke and permanent loss of sight in the army, and finally became more or less blind, that it is quite desirable for the expert in examining such cases to be supported by greater authority than he is likely to discover in any text-books or accessible literature. In point of fact there has never been reported in the vast extent of ophthalmic literature but a single undeniable case in which sunstroke had been followed by permanent blindness, and only six others in which the eyes were ophthalmoscopically examined soon after the attack. In all of these optic neuritis was distinctly marked, and in several vision was reduced to a low degree; yet ultimately, all six recovered perfect vision without much, if any, treatment.

Two or three cases illustrative of the assertions of pension claimants were presented in the paper, and the precise reasons for granting or not granting a pension were reported in full. Judging from the history of these cases insolation had nothing whatever to do with the loss of sight; while from historical and scientific records it appears extremely doubtful whether the disease ever has any permanent effects on the sight.

The frequent allegations of patients "losing their sight during a sunstroke," or of "a dimness coming over their eyes," are simply descriptive of the incipient stage of unconsciousness and are untruthful in a scientific point of view. These recollections become in later years the basis of pension claimants' assertions that their vision was seriously affected by sunstroke.

Dr. Spalding expressed the opinion that these were false, and hoped that the members would support expert examiners against the insults of politicians and claimants' friends in refusing to grant pensions for asserted blindness fifteen or twenty years after a sunstroke.

A CASE OF PROBABLE QUININE AMAUROSIS,

by DR. D. B. ST. JOHN ROOSA, of New York.

The patient was a young lady who had been living in a malarious district. While in Washington she had an attack of intermittent fever. Some time after this she was seized with convulsions and unconsciousness. It was believed to be a case of malarial coma, and thirty grains of sulphate of quinine were administered by the rectum on four occasions. On the third day consciousness was restored, but she was then unable to distinguish light from darkness. The pupils were dilated. She had been taking quinine and iodide of potassium before I saw her, which was October 18, 1886. Vision was slightly recovered and she could count fingers at four feet. On ophthalmoscopic examination the optic papillæ were found small, the vessels very small, but no exudation was seen. Quinine three times a day with a hypodermic injection of strychnia was given. The dose of strychnia was gradually increased to 1.24 of a grain and kept at that for some time. Vision gradually improved. It was at first excentric, but by December 10th she had centric vision of $\frac{20}{LXX}$. The papillæ was still white and the vessels small. The treatment was continued. She returned to her home and now states that she can see almost as well as she ever could. The urine was tested in this case several times with negative results.

DISCUSSION.

DR. EMIL GRUENING, of New York. In the latter part of June I saw a lady, fifty years of age, who had been given thirty grains of quinine in one dose. When she awoke in the morning she was blind and deaf. She was deaf for about twelve hours and absolutely blind for twenty-four hours. I saw her about five days after the attack. The fundus was apparently perfectly normal in both eyes. Central vision was normal, but the field was much contracted in all directions. It does not seem to me that the ischæmia which has been described in the more severe cases, should necessarily be present in the lighter cases of quinine amaurosis.

CLINICAL CONTRIBUTIONS TO THE STUDY OF RING SCOTOMA,

by SWAN M. BURNETT, M.D., of Washington.

The speaker gave the histories in full of two cases of ring scotoma which he had followed for the space of two years. In one case there was a history of syphilis and in the other not; in both there was choroiditis with vitreous opacities. In one case there were no gross changes in the choroid, in the other the changes did not correspond with the defect in the visual field. In one case only one eye was affected, in the other the affection was binocular. In one case the trouble began as a typical right hemianopsia with left semi-annular scotoma. The central clear spot more or less oval in form, 10° to 20°, was never through all the changes diminished in size. All who have written on the subject (a full bibliography was appended to the paper) have placed the pathological process inside of the eye, though in none have the changes in the choroid, manifest under the microscope, been sufficient to warrant such a conclusion, and in none have the changes in the form of the visual field been followed so closely or so long as in these cases, eighteen diagrams of the fields at various times being exhibited. The course of the nerve-fibre in the tract chiasm and nerve, as demonstrated by Bunge, Lamelsoker, Leber, Vassius and others, particularly in the somewhat analogous condition of central scotoma which in nearly every instance coincided in form and size with the central clear space in these cases seems to justify the assumption that the fibres supplying the intermediate parts of the retina were hindered in their function either from a localized neuritis or by pressure of the adjoining parts.

DISCUSSION.

DR. HENRY D. NOYES, of New York. A young lady, aged seventeen, came to me complaining of pain and dimness of sight in one eye. The ophthalmoscope showed no material lesion, but with the perimetre I discovered a ring scotoma. There were no local lesions, no symptoms of brain trouble, and no evidence of hysteria. Further examination showed signs of orbital neuritis. I based this view chiefly on the fact that pressure of the globe backward elicited unquestionable pain. This continued for at least two weeks. The ring scotoma subsequently entirely disappeared, and vision was restored to the normal. I am satisfied that ring scotoma may have an ex-ocular origin. When we search for these cases more carefully I think that we shall find that they are not so extremely rare as has been supposed.

DR. C. S. BULL, of New York. Some time ago I reported a case which would come under the same category as those of Dr. Burnett. The patient, a man of thirty-six years of age, when two years of age, injured the right side of the skull by a fall. Vision of right eye was impaired, and a convergent squint followed. He could count fingers at two feet with the right eye. In 1878 he had a compound depressed fracture over the left parieto-occipital region of the skull. Trephining was resorted to. This was followed by convulsions which have since grown less marked. He noticed that he could not see through a part of the field of the left eye. The ophthalmoscope shows a neuro-retinitis of low grade in the left eye. The field was normal for twenty degrees around the point of fixation, then there was an irregular defect in the field for fifteen to twenty-five degrees all around, and outside of this the field was normal.

DR. W. F. MITTENDORF, of New York. Attention has recently been called to the fact that peripheral annular scotomata are often present in cases of chronic glaucoma. I have examined five or six cases of glaucoma with this in view, and have found it in one instance.

DR. O. F. WADSWORTH, of Boston. A case which I recently published seems to show that the lesion in these cases may be situated in the nerve. A young man, aged twenty-three, was run over by a heavy wagon, one wheel passing over his chest. I saw him forty-eight hours later. There was slight haziness of the retina and some slight, thin hæmorrhages in the right retina. There was a central scotoma. In a short time the scotoma resolved itself into a ring scotoma. This condition continued for at least two years afterwards. There was absolutely no ophthalmoscopic change to be detected.

THE SO-CALLED ORTHOPÆDIC TREATMENT OF PARALYSIS OF THE OCULAR MUSCLES,

by DR. CALEB S. BULL, of New York.

Reference was made to the fact that the use of galvanism in the treatment of paralysis of the ocular muscles was unsatisfactory, on account of the impossibility of localizing the current to the affected muscle. The method of Prof. Machelle was then described. In this plan the muscle is seized with fixation forceps and the eyeball moved backwards and forward in the direction of the ordinary action of the affected muscle. This procedure produces some pain and slight irritation. The pain is largely relieved by the use of cocaine. The speaker had employed this method in twenty-one cases of ocular paralysis, due to various causes. The paralysis was entirely cured in eight cases; partially relieved in seven cases, and in six cases the treatment was entirely valueless.

RECURRENT PARALYSIS OF THE MOTOR OCULI,

by DR. O. F. WADSWORTH, of Boston.

Pauline and Frances were twins, born of healthy parents. In June, 1874, when the twins were three years of age, they had scarlet fever, and this was followed by a discharge from the ear. In each case a slight discharge from one ear continued. In 1877 Frances began to complain of headache, which recurred frequently until three months later, when she had a convulsion. The convulsions were repeated. Six months after the first convulsion she complained that she could not see. Examination showed well-marked optic neuritis. The headache and convulsions gradually ceased, but she remained blind. She was again seen in 1879, and found to be in good health, with the exception of the blindness.

Pauline, after the attacks of scarlet fever in 1874, had headache recurring every month or so. On February 24, 1879, she was brought to the hospital with the history that she had suffered with daily pain in the head for two weeks; this was referred to the supra-orbital region. It would commence about noon, then intermit, recur again about five o'clock, and continue for several hours. There was vomiting on the first two days of the attack, and there was a slight discharge from the right ear. She was seen one month later. The headache had recurred every two or three days. There was then paralysis of all the branches of the right motor oculi nerve with ptosis and divergence of the right eye. By February, 1887, the headaches had diminished in frequency, and for the last few years she has had three or four attacks a year, the more severe being accompanied by ptosis and dilatation of the pupil. It was subsequently learned that with each severe attack there was a free discharge of ill-smelling fluid from the right ear. On May 1st, the right ear was examined and a polypus filling the meatus found and removed. The writer had been able to find only fifteen cases of this affection on record. Of this number four were males and eleven females. The period between the attacks was variable and irregular. In several instances there was evidently a persistence of a certain amount of paralysis between the attacks. This was noted in the case just described. There has been no instance of permanent relief, and three of the cases have terminated fatally.

As to the cause of the affection, the results of the autopsies point to a basal origin. In one case plastic exudation surrounded the right motor oculo-nerve; in another case the right oculo-motor nerve was pressed upon at its point of emergence from the crus cerebri, and in the third case there was a fibro-chondroma which had developed in such a way as to separate the fibres of the right oculo-motor nerve without destroying them. In the case reported, the speaker thought that there was an evident association of the paralysis with the chronic aural trouble.

HYPERÆMIA IN MUSCULAR INSUFFICIENCY,

by J. A. LIPPINCOTT, of Pittsburgh.

The speaker reported several cases of localized hyperæmia of the eye, which he thought were due to

weakness of the muscles. The grounds on which he based this view were the form and location of the spot of hyperæmia and its disappearance along with other evidences of the muscular insufficiency.

The Society then adjourned until eight o'clock in the evening.

EVENING SESSION.

CASES OF ACUTE PRIMARY GLAUCOMA; OF HEMORRHAGIC GLAUCOMA, AND OF SECONDARY GLAUCOMA,

by DR. W. F. NORRIS, of Philadelphia.

The first case reported was that of a married woman, aged fifty-two years, who was admitted to the Will's Eye Hospital with acute glaucoma of the left eye. The attack was of twelve days duration. Vision was much impaired. The right eye was entirely quiet, and presented a narrow iridectomy upwards. In August, 1875, a severe attack of glaucoma had suddenly occurred in the right eye, and on the fifth day, iridectomy had been performed. Since then the eye had given no trouble. When admitted to the hospital, the patient was in a feeble condition. She was put to bed, a leech applied and eserine instilled. The eye improved and became quieter. The cloudiness of the cornea and the other symptoms remaining, iridectomy was performed twenty-eight days from the commencement of the attack. A year later, she had a severe attack of pain not relieved by eserine, and sclerotomy was performed. The eye continued to give trouble from time to time, and it finally became necessary to enucleate it.

Primary Hemorrhagic Glaucoma. Miss B., age seventy years, was seen in February, 1867, with marked hemorrhagic retinitis and incipient cortical cataract. She stated that she had a sudden loss of vision two years previously. The present attack of loss of vision came on suddenly ten days before, when the patient was stooping. Examination showed numerous hemorrhages into the retina. One month later, the right eye was more cloudy, the tension increased, and there was some hemorrhage into the anterior chamber. Iridectomy was then performed. The wound did well until the fourth day, when there was a sudden attack of pain. On the ninth day, apparently without exciting cause this symptom recurred. After this there would be an exacerbation every few days. The eyeball was subsequently enucleated, the patient dying a year or two later with apoplexy.

Secondary Glaucoma. After successful operation for cataract. A man aged sixty-six, had been operated on for cataract in both eyes some time before coming under observation. This had been done in England, both operations having been successful. Some eighteen months later, the right eye had been operated on as a needle operation, and since then it had not been free from irritation. When seen, the right had lost the perception of light, and the left eye presented signs of sympathetic irritation. The right eye was enucleated, and this relieved the irritation in the left eye. The patient now sees fairly well.

A number of micro-photographs showing sections of the eyes removed in these cases were exhibited by means of a lantern.

DR. B. ALEXANDER RANDALL, presented the notes of a case of

SARCOMA OF THE EYE-LID,

simulating a meibomian cyst, occurring in a man about forty-one years of age, who came under observation in 1885, with the history of two operations in the previous three years for the removal of a cyst. The tumor had the position, size, color and apparent *fluctuation* of a chalazion, but a vague grayness, suggested pigmentation, and led to its total removal by a V-shaped incision through all the tissues of the lid. Section proved the tumor to be a solid encapsuled sarcoma of large spindle cells. The patient passed out of sight for two years, and then returned with recurrence very like the original, which had been treated in the interim as chalazion. The outer half of the lid had now to be removed, and the tumor was found to be of the same nature as before, and again encapsuled. The meibomian glands at both operations seemed to be entirely normal, and the tarsus was entirely uninvolved.

Dr. Randall also presented some of the ophthalmoscopic cases of Cilio-Retinal vessels, with the remark that they were far from rare, and that the occurrence of such an origin of even a principal artery or vein, supplying different quadrants of the retina, had come to notice. As to the origin of these vessels; in two cases they could be distinctly seen to join the network of the choroid. The reported cases examined anatomically have been seen to arise directly from a short ciliary vessel. Photo-micrographs of such a case in the collection of Dr. W. F. Norris, were shown.

Dr. Randall also called attention to the Hohlschnitt of von Jaeger in cataract extraction, as differing in no essential from the modified linear operation, except in the knife with which it is made. He asked attention to the knife, with the claim that with it almost all the usual modifications of the linear extraction could be made, but that no aqueous need be lost until the completion of the incision, and consequently that the cut could be made more safely and smoothly than was possible with the Graefe knife. As illustrative of the perfection of the healing, he demonstrated a photo-micrograph of a Hohlschnitt executed by von Jaeger himself, which he had prepared in Professor Alt's labratory about a year after the operation.

DISCUSSION.

DR. H. KNAPP, of New York. I have used Jaeger's knife, but I have not found the advantage which the author has claimed. I think that it is simply a modified small Baer's knife. In my experience it has been more difficult to pass a larger knife through the anterior chamber than it is to pass a Graefe knife. By practice, the section can be completed in one cut by the Graefe knife, but I do not consider this necessary.

DR. H. D. NOYES, of New York. I agree with the last speaker as to the greater facility in passing a narrow knife. A narrow Graefe knife gives better control of the movements necessary in making a proper section than any other knife which I have tried.

DR. S. THEOBALD, of Baltimore. It is probable that the greater facility in the use of the narrow knife over the triangular knife may be due to the fact that in using the latter, we are doing two things at once. We are attempting to pass it across the anterior chamber, and at the same time, to complete the section. With the Graefe knife we transfix the eye and then make the section.

(To be continued.

AMERICAN NEUROLOGICAL ASSOCIATION.

THIRTEENTH ANNUAL MEETING AT LONG BRANCH.

FIRST DAY, JULY 20, 1887.— MORNING SESSION.

DR. CHARLES K. MILLS, the retiring President, addressed the members present, remarking that heretofore the number of members of the Association had been limited to fifty, but by an amendment of the constitution the number had been extended to one hundred; which he thought would augument still further the usefulness of the Association. The speaker stated that he had received a letter from Benedict, of Paris, in reference to the brains of criminals and idiots, which he (Dr. Mills) had presented at the meeting last year, as Dr. Benedict feared he had been somewhat misunderstood in regard to his views upon the subject.

DR. LANDON CARTER GRAY, of Brooklyn, N. Y., the President of 1887 and 1888, was then presented, and made an address in which he drew attention to the steady march of science in neurology, contrasting the work done in this line by the American physicians with those of Europe and other countries, and showing that American physicians were in advance in forming societies for the advancement of the study of neurology and scientific discussion on the subject.

He stated that Germany had only one society, France had not any by that distinctive name, and it was only one year ago that one was formed in England. Italy, in the broad sense of the word, had none. The speaker called attention to the increased use of electricity in nervous disorders, and also the advantages afforded by the microscope in the study of the brain; drawing attention to the fact of chairs being established almost generally in our colleges for this branch of medicine, whereas in previous years a few lectures alone had been deemed sufficient.

DR. E. C. SPITZKA, of New York, read a paper

ON SOME POINTS REGARDING THERAPEUTICAL AND OTHER INJURIES OF THE BRAIN.

The speaker drew attention to the impunity with which portions of the brain could be removed, even without antisepsis, and no evil results follow; also the use of the trephine and the insertion of the trocar and hypodermic needle for the exploration of the brain in tumor or abscess; the methods of localization in case of disease of this organ.

He remarked that uniformly he had, during experiments upon dogs, been able to abuse the brain to an extent which some years ago would have been incredible; the doctor quoted a case in which a diagnosis was made of tumor of the brain, and in which the patient was trephined and an exploring needle inserted, but without result. The button of bone was replaced and the man made a good recovery from the operation, but died three months after; the autopsy proved the correctness of the former diagnosis. Under the microscope the prepared specimen at the seat of trephining showed three thin bluish lines where the needle had been inserted three months before, showing that it had not been inserted quite deep enough to reach the tumor. The button of bone was slightly movable, union not having taken place in its entire circumference. Unfortunately, the specimen had not been retained. From this he thought it evident that in young persons, even under discouraging circumstances, as wounding of the dura by the saw, parietal hernia and lifting of the button, the dura makes successful efforts to agglutimate the reinserted button and restore the integrity of the calcarium. The speaker considered there was less danger of hernia of the brain if a fair-sized-piece of bone were removed, than a small piece; quoting a case of Dr. Graeme Hammond to illustrate the statement. He drew attention to the fact that in experimenting on dog's brains by injecting poisonous or anti-septic fluid into this organ, that abscess or disease was not necessarily created at the seat where the injection was made.

In the experiments made, coarse and fine needles had been used and coarse substances injected with great impunity, in one instance ordinary street mud was used, but the dog recovered without any untoward symptoms. The dog was finally shot four months after because of *mange;* on examination of the hardened brain two masses of mud were found but no trace of the channel where the needles were inserted.

In two other dogs where the operation had been performed, the channel of the needle remained patent and the injected hemispheres had become atrophied; this he could not account for, but thought it valuable to bear in mind. During these experiments upon dogs he had found that the more the dog's brain is abused the more it can bear the operation; that is to say, the second trephining is less dangerous than the first, and a third less so than the second. In two cases he had found the growth dwarfed, and symptoms of imbecility; unfortunately, these two died during his absence from the city, owing to neglect.

From the writer's experience with the human and experimental pathology mentioned, he was induced to draw the following conclusions:

(1) That exploratory needles should never be introduced in the internal capsule, the contiguous ganglia, or the lateral ventricles, merely for exploratory purposes unaided by positive clinical evidence of the location of disease.

(2) That exposure of large surfaces are not feasible in persons with feeble vascular walls, owing to the danger of intra-cranial hæmorrhage.

(3) That buttons of bone re-inserted under aseptic precautions are, even in the event of non-union, entirely harmless.

(4) That in young persons buttons of bone may become re-united to the calvarium, even though perfect coaptation may not be assured.

He would add that he had very recently observed how desirable it is, in the event of trephining for the relief of cortical irritation, that on removal of the latter the button of bone be replaced.

DR. G. HAMMOND remarked that he thought in all cases of trephining the button of bone should be re-inserted. He quoted a successful case of Dr. Weir, in which a large piece of bone had been removed, and afterwards re-inserted with the most desirable results; the portion replaced having united firmly to the skull.

DR. LLOYD asked Dr. Spitza if he had ever punctured the brain of a child for hydrocephalus, as some time ago he had a patient brought to him for this purpose.

DR. MILLS thought it perfectly right in some cases to re-insert the button of bone, but at the same time the condition of the dura must necessarily guide us in the matter as to the extent of inflammation exhibited. He quoted one case in which the piece of bone removed was four by three inches, but there was a cen-

tral depression in the bone removed, and it was deemed necessary in order to re-insert the bone that this depressed portion be removed; the bone, however, was not replaced. In regard to the remark made by Dr. Spitzka as to the animal brain being more resistant after surviving the first operation, that had been corroborated by his own experience. The speaker mentioned a case in which the portion of bone removed was the largest he had seen, and also with considerable loss of blood, the patient made a good recovery from the operation, but afterwards died from pneumonia. He considered Dr. Spitzka's paper an exceedingly interesting one, and worthy of thorough discussion.

Dr. Spitzka, in closing the discussion, said that in those cases where it was not deemed advisable to reinsert the bone removed, there was a method, he believed due to McEwen, of sprinkling the exposed surface of the dura with bone-grafts. He thought that even should a bone-graft drop into the brain substance it would do harm, as the bone dust in trephining in some cases has not been entirely removed, but has caused no disturbance.

As to the question asked by Dr. Lloyd regarding puncture of the brain for hydrocephalus, he would not hesitate to insert a large trocar into the brain substance. Although he had not performed the operation, he had seen Dr. Detmold do so, and he had himself tapped large tumors of the brain with the most satisfactory results.

Dr. James J. Putnam, of Boston, read a paper on

NOTES OF A RARE CASE OF DYSTROPHY OF THE FACE AND HEAD.

The case, he remarked, was one probably of hyperostosis of the cranium, occurring in a young woman twenty-one years of age. Her health was apparently good, and there was no history of syphilis. Her mother, however, suffered with her head. The patient's first symptom was severe and intense pain in the head. Enlargement and protrusion of the eye and also of the head was first noticed about two years after the beginning of the headache. Three years ago her teeth began to fall out, and at the time the speaker saw her she had but one remaining tooth. Two years since a purulent discharge from the ears appeared and she could not distinguish the sound of a tuning-fork. Two years after the first symptom of the disease appeared she had a miscarriage, and one year later menstruation ceased. The writer presented photographs of the skull of the patient, showing both front and profile views, plainly exhibiting the extent to which the abnormal growth had reached, noticeably above the ears. There was œdema of the left eyelid, the eye extremely protruded, so that more than half the globe projected. There was no evidence of any paralysis of the nerves, except that the tongue moved slightly to one side; there is a well-defined opacity in the upper part of the lens of the left eye, which may be of importance.

Dr. Putnam then make a few remarks on a

SARCOMATOUS TUMOR OF THE BRAIN ATTACHED ON ONE SIDE TO THE SPHENOID BONE,

which had come under his observation.

The patient had had periodical attacks of headache for eighteen months previously, which he thought perhaps might be ascribed to this cause. During the time he had seen her she suffered from intense headache and neuritis, and then eventually a slight degree of facial paresis on the opposite side. In the last two months had complained of pain in two fingers of the left arm, the side of the tumor. At the autopsy, on examination of the brain, there was exhibited a shining black mass representing a flattened tumor; this contained blood with a small number of cysts, the brain being compressed in a remarkable manner, and in spite of this extreme compression no distinctive symptoms presented themselves until within the last two months before death. It is an interesting surgical question as to whether in this case an exploratory operation would not have been justified.

Dr. Spitzka remarked, that in one case where the numbness in the fingers occurred, as mentioned by Dr. Putnam, a tumor had been discovered in the brachial region. He also called attention to the specimen held in one of the English museums, in which the orbital cavities were almost entirely obliterated, owing to the excessive hyperostosis, which was of a somewhat spongy character.

Dr. Putnam said the autopsy was confined to the head alone; he thought Dr. Spitzka's remark just; as he could call to mind a case in which a tumor of the brain was pressing on both hemispheres, and it presented no symptoms but pain and numbness in one wrist; but in the case first mentioned the pain was not in the ulnar nerve, it was only in the two middle fingers; the speaker mentioned Charcot as making this observation many years ago.

(To be continued.)

Recent Literature.

Dose and Price Labels of all the Drugs and Preparations of the U. S. Pharmacopœia of 1880. With many unofficial articles that are frequently called for as medicines or used in the arts. For Pharmacists, Physicians, and Students. Second edition, By C. L. Lochman. Bethlehem, Pa.: 1887. $1.25. 200 pages.

The most appropriate use of such a work as this, is to cut out the labels from their pages, which are printed on one side only, and paste them on bottles or on other suitable places in a dispensary.

The labels have nothing on them which might not be found in a dispensatory or similar book, but the information they afford is reached quickly, and is of a practical nature, suggesting in many, if not all cases, essential points regarding the properties of the substances, and some of the precautions to be taken in their use.

Under hydrochlorate of apomorphine, for example, we are told that: "It is the salt of an artificial alkaloid prepared from morphine." Then follows its dose as an emetic and as an expectorant. "The solution should always be freshly made. Soluble in 6.8 parts of water, and in 50 of alcohol." The lettering and two exclamation points are intended to suggest that it is an active substance. A space is left for the prices.

The work seems to have been done with care, and the author must have devoted a good deal of time to its compilation. For a student's collection of drugs, it would be excellent.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 4, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

REPORT OF THE SEYBERT COMMISSION.

THE preliminary report of the Commission appointed by the University of Pennsylvania to investigate modern spiritualism, in accordance with the bequest of the late Henry Seybert, has lately been published. It will be remembered that Mr. Seybert, who, during his lifetime, was known as an ardent defender of modern spiritualism, left a bequest to the University of Pennsylvania to found a chair of philosophy in that University, and to the gift added a condition that the University should appoint a Commission to investigate the claims of modern spiritualism. A Commission of ten men was accordingly appointed, and it is safe to say that ten better names could hardly have been chosen. The medical profession is represented on the Commission by William Pepper, Joseph Leidy, George Koenig, James W. White, Calvin Knerr, and S. Weir Mitchell; Dr. Pepper, as Provost of the University, being Chairman, and George S. Fullerton, Secretary.

The Commission has spent several years in investigating phenomena appearing under the mediumship of the best exponents of modern spiritualism, whose services they could command at any reasonable price. Among these was the noted Henry Slade, whose performances in Germany, several years ago, so befooled Zoellner and three of his associates, Weber, Fechner, and Scheibner, and were the basis of a book subsequently published by Zoellner, which has had a very wide circulation, and is much cited by believers in spiritualism.

The American investigators, after putting these mediums to severe tests (in which, however, with due fairness, they were careful to comply with the usual "conditions,") and having matched Slade's performances with those of certain prestigiators (as the juggler, Kellar), and to the advantage of the latter, conclude that, as far as their studies and researches, now extending over more than three years, are concerned, the mediums have failed to make good their claims to anything more than consummate fraud and deception. In conclusion, they say: "We beg to express our regret that thus far we have not been cheered in our investigations by a single novel fact; but, undeterred by this discouragement, we trust to continue them with what thoroughness our future opportunities may allow, and with minds as sincerely and honestly open as heretofore to conviction."

In an appendix, are given full details of the interview of one of the members of the Commission with Professors Fechner, Scheibner, and Weber, the surviving colleagues of Professor Zoellner in his experiments with Dr. Henry Slade. There would seem to be evidence that Zoellner was of unsound mind at the time of those celebrated experiments; that Fechner was old and feeble and partially blind, and relied upon Zoellner's observations; that Scheibner was also affected with imperfect vision, and not entirely satisfied in his own mind as to the phenomena; and that Weber was advanced in age, and did not even recognize the disabilities of his associates. "No one of these men had ever had experiences of this sort before, nor was any one of them acquainted with the ordinary possibilities of deception."

There is also an interesting account of an investigation of the power of mediums to answer the questions contained in sealed envelopes, the result of which goes to show that these mediums are not too honest to resort to such tricks of opening and reading sealed letters as rendered famous that arch humbug of the days of Marcus Aurelius, Alexander, of Abonotichus, whose clever deceptions are recorded by Lucian. The marvels of "Materialization Séances" are made sufficiently ridiculous in the report of Rev. Horace Howard Furness, with which the book ends. On the whole, we should think that this little volume would be anything but pleasant reading to many who have committed themselves to this superstition; that it will have a wholesome, helpful effect on many others, we do not doubt.

THE DOCTRINES OF "CHRISTIAN SCIENCE" AND "MIND-CURE."

THE Rev. J. M. Buckley, D.D., a prominent preacher of the Methodist Episcopal Church, and at present editor of one of the most important of the denominational religious journals of this country, has published, from time to time, articles on the subjects of mind-reading and other psychopathic phenomena, to one of which we have before referred, characterized by a clearness of judgment and a robustness of common sense which have not always been found in gentlemen of his cloth in the treatment of such subjects. A few months ago, an article in the *Century* by this author treated clearly and dispassionately of the so-called "Faith-Healing and Kindred Phenomena," and in the July number of the same magazine is a paper by him on "Christian Science and Mind-Cure." The value of the latter paper consists in part in the fact that it contains many extracts from the writings of

the exponents of the systems themselves, who may be supposed to give the principles of the science with as much cogency as such statements are capable of receiving.

The extracts, which are numerous, indicate, on the part of their editor, an expenditure of time and study which few people are able to give to the subject, outside of those who are working it for what they can make out of it. We are reminded, in this connection, that it takes eight hundred dollars to hear from the very *pontifex maxima* herself, the thirty lectures in which the entire subject is covered, and whereby one may become an adept in this art.

There are teachers who will "fit" you for less money, even for one hundred dollars, and whomever you go to, the others assert you are not getting the real thing. Occasional suits for infringement of the copyright of one teacher by another tend to further the increase of various "schools" in the art, between which schools the vital point at issue, is whether the money shall go into the pocket of Mrs. A. or Miss B., in either case, the founder and chief member of the "school."

Among the fundamental principles of the mental healers, as expressed in their own words, space permits us but a few extracts:

"Anatomy, Physiology, Treatises on Health sustained by what is termed material Law on the husbandmen of sickness and disease . . . when there were fewer doctors and less thought was given to sanitary subjects, there were better constitutions and less disease." — "We are told that the simple food our forefathers ate assisted to make them healthy; but that is a mistake." — "Because the muscles of the blacksmith's arm are strongly developed, it does not follow that exercise did it, or that the arm less used must be fragile. If matter were the cause of action and muscles without the co-operation of mortal mind could lift the hammer and smite the nail, it might be thought true that hammering enlarges the muscles. But the trip-hammer is not increased in size by exercise. Why not, since muscles are as material as wood and iron?"

"Suppose the patient should appear to grow worse. This I term *chemicalization*. This the upheaval produced when Immortal Truth is destroying erroneous and mortal belief. Chemicalization brings sin and sickness to the surface, as in a fermenting fluid allowing impurities to pass away. Patients unfamiliar with the cause of this commotion and ignorant that it is a favorable omen, may be alarmed. If such is the case explain to them the law of this action."

Perhaps, however, the cream of the whole article is the following, which constitutes a portion of a prayer, printed *verbatim*, capitals and all, from a textbook on a "Mind-Cure," issued by the President of the "New York School of Primitive and Practical Christian Science," who states that his school will be free from "eccentricity, pretension, and fanaticism."

"PRAYER FOR A DYSPEPTIC."

"Holy Reality! We BELIEVE in thee that thou art EVERYWHERE present. We *really* believe it. Blessed Reality, we do not pretend to believe, think we believe, believe that we believe. WE BELIEVE. Believing that thou art everywhere present, we believe that Thou art in this patient's stomach, in every fibre, in every cell, in every atom, that Thou art the sole, only Reality of that stomach. Heavenly, Holy, Reality, we *will* not try to be such hypocrites and infidels as every day of our lives to affirm our faith in Thee and then immediately begin to tell how sick we are, forgetting that Thou art everything and that Thou art not sick, and, therefore, that nothing in this Universe was ever sick, is now sick or can be sick. Forgive us our sins in that we have this day talked about our backaches, that we have told our neighbors that our food hurts us, that we mentioned to a visitor that there was a lump in our stomach, that we wasted our valuable time which should have been spent in Thy service, in worrying for fear that our stomach should grow worse, in that we have disobeyed thy blessed law in thinking that some kind of medicine would help us. . . .

"Lord help us to believe that ALL Evil is utterly unreal; that it is silly to be sick, absurd to be ailing, wicked to be wailing, atheism and denial of God to say 'I am sick.' Help us to stoutly affirm with our hand in Your hand, with our eyes fixed on Thee, that we have no dyspepsia, that we never had Dyspepsia, that we will never have Dyspepsia, that there is no such thing, that there never was any such thing, that there never will be any such thing. Amen."

MEDICAL NOTES.

— A performance of "The Golden Legend," personally conducted by the composer, Sir Arthur Sullivan, and rendered by the most eminent musical talent in London, took place the 13th ult., in aid of Middlesex Hospital, and netted quite a sum for that institution.

— Dr. Russell, medical officer of Glasgow, is reported to have said, that, during the last ten years over a million of articles (from persons affected with every kind of contagion known in this country) have passed through the Glasgow laundry, and that he has never known a case of interchanged disease, although the women engaged in the laundry have occasionally suffered from handling the linen before the boiling process.

— Dr. Castro, of Italy, states (*Annal. d'hygiéne publ.*, ser. 3, t. xvii. pp. 48–50) that he recently had occasion to inquire into the presence of scars as the result of leech bites. He made thirty-seven experiments on different individuals, with the result that in several cases it was impossible to discover a scar by the naked eye. But in such cases the scar became evident after rubbing the skin with tincture of mustard, which reddens the skin surrounding the scar leaving the scar white.

— Dr. Van Harlingen, in the *Polyclinic*, answering the question, "What forms of skin diseases leave scars?" thus recapitulates his observations: "cysts, wens, the deeper forms of dermatitis, furuncle, anthrax herpes zoster, acne, ecthyma and tinea favosa may at times and under certain circumstances give rise to the formation of scars. Scrofuloderma and syphiloderma in some forms, the various forms of lupus, carcinoma and sarcoma almost inevitably lead to scarring. Another class of diseases which may indirectly, though not directly, give rise to scars through scratching are the pruriginous affections *par excellence*, that is, pruritus and eczema. These may be followed by cicatrices and other results of scratching when the lesions themselves might not leave anything which could be called a cicatrix."

— In the *Practitioner* for May, 1887, Mr. R. C. Holt published notes of five cases of meningitis occurring in children, in three of which cases success fol-

lowed the employment of an ointment containing ten per cent. of iodoform rubbed into the shaven scalp. In the three successful cases the bones of the head had not coalesced, and in all the cases the treatment was not commenced until the disease was well marked. The results appear to encourage the further trial of this treatment, and as soon as possible after the diagnosis is made.

— Dr. H. T. Griffith gives in the *Lancet* the result of 600 consecutive observations as to the position of the nipple in relation to the ribs. They were all taken, the patient being in the recumbent position. The *fourth space* is shown to be the average position in male and female adults, the range being from the third to the fifth rib in adult males, and from the third to fifth ribs in adult females. In children the range was the same as in adult females, but the average position was at the *fourth rib.*

—According to a Western contemporary, a church in Wisconsin was built under considerable stress for money, and it was found that the cellar was damp, no drain having been put in to remove the ground-water. A parishioner remedied the difficulty by giving the church a large number of champagne bottles from his own cellar. The bottoms were knocked deftly off and the necks shortened. The neck of one bottle was placed in the bottom of another and so until a drain was constructed, which has kept the church "extra dry" ever since. The same method is said to have been used in England.

— An unfortunate medical quarrel has been ventilated through the public press in Washington. The trouble as stated is as follows: Last spring Dr. Sowers, of Washington, criticised, through the newspapers, the President's manner of living, from a medical point of view. Surgeon-General Hamilton, of the Marine Hospital Service, preferred charges against Dr. Sowers before the Medical Association in Washington for unprofessional conduct. These charges were not sustained by the majority of the committee appointed to investigate Dr. Sowers' case, although a minority report was prepared convicting him of unprofessional conduct. Dr. Sowers has now filed charges with the Association against Dr. Hamilton. He states that Dr. Hamilton has violated two articles of the Association regulations in having shown to ex-Representative Hazelton the charges which he was about to prefer against Dr. Sowers last April. This was done, it was charged, with the full knowledge that Mr. Hazelton and his family were patients of Dr. Sowers, and was intended to lower him in the estimation of his patients.

— *Science* publishes the following set of test questions in "Physiology," given to the classes of boys and girls from eight to ten years of age in the public schools of a "prominent Eastern city."

1. How can it be proved that nicotine is a poison? 2. Why are cigarettes especially harmful? 3. Is alcohol a food? 4. What is the effect of disuse upon a muscle? 5. Under what names is opium sold? 6. Under what names is alcohol drunk? 7. What is the difference between a food and a poison? 8. Is anything gained by changing from one narcotic to another? 9. What is the effect of beer as a drink? 10. How does cheerfulness help the muscle? "This is the examination-paper at the end of the first year's elementary instruction in physiology. Of ten questions, eight relate to drinking and smoking: the physiology is a mere side issue. These children, who ought to have about as much knowledge of such matters as they should of the methods in vogue at the stock exchange, remarks our contemporary, are actually forced to learn by rote the details of human vice; and that, too, under the name of 'physiology,' the only science which they learn. Unconsciousness, *naïveté*, is the symbol of childhood. The fact that physiology, even if well taught, tends to destroy this trait, is the chief objection to its early study. Instruction such as the above implies, crushes the most valuable trait in the child, directs its curiosity to what is morbid, and forces into precocious development all its dangerous elements. Not enough that the newspaper and the dime novel proclaim in glaring colors the story of crime and sin: some notion of the perversity of human nature must be mixed with the food of babes."

— "Without the doses three times a day, the service would not go on; they unite the attention of doctor, patient, nurse, and friend in a periodic series of efforts, something not unlike those little yells a group of sailors make in turn when they are hauling hard on a cable, without which it appears the cable would never come along, though there is no apparent force in the noises they make. A doctor without physic is like a priest without a creed, or a poet without rhyme."

"Classification of Disease. — He cannot classify diseases, because what he knows of them is not comparable knowledge. For while one disease is a pain in the leg, and another a growth in the stomach, and another a spider in the skin, the classification of them is worse than mixing incompatible — it is mixing things indifferent. It is like trying to mix the solar spectrum and the key of C major with essence of peppermint."

"Advice gratis. Three kinds. Sympathetic — Let me help you. Apathetic — Do as you like. Antipathetic — Get thee and hang thyself."

"Knowledge is not power. Power arises by training in the use of knowledge. Consider the difference between training and teaching. The teacher carries over the things he knows, and fixes them in the learner's memory; the trainer takes what is in the memory, and converts it into an organ for the pupil's own use."— *Extracts from Pilocereus Senilis (an old man cactus) a series of papers by Walter Moxon, F.R.C.P.*

NEW YORK.

— During the second week of the extra summer service of the Board of Health 4,170 houses and 30,441 families were visited by the physicians of the

corps, who treated 1,036 cases of illness and gave 1,022 prescriptions. Eleven additions have been made to the corps, this bringing it up nearly to the desired number of fifty.

— In enforcing the new regulations requiring the removal to the hospital of all diphtheria cases which cannot be properly isolated at home, the sanitary authorities recently found it necessary to call in the aid of the police, in order to remove two children suffering from the disease, from a crowded house in Broome Street, as the father and friends of the patients attempted to interfere with the officers sent for the purpose.

— The father of a child which died of diphtheria and the undertaker who had charge of the funeral of the child have both been held in $300 bail, to await trial for violating the law relative to burials of those dying of contagious diseases. The arrests were made on the complaint of a sanitary inspector of the Board of Health, who had warned the parents of the sick child to keep it isolated and have a private funeral in case of its death. His warning was disregarded, however, and the body was exposed at the funeral in a room crowded with people. The case occurred in a tenement-district, and there were more than ten families living in the house. At its last meeting, the Board of Health ordered that a notice calling attention to the sections of the Sanitary Code in reference to persons dying from contagious disease should be printed on the back of all burial permits.

— At the Chambers Street Branch of the New York Hospital, a patient suffering from sunstroke who had a temperature of 108.8° and had had violent convulsions for twelve hours, was recently bled to the extent of eighteen ounces, with the effect, apparently, of saving his life; although twice afterward the temperature went up as high as 105°. A case very similar in character which was brought to the same hospital some time since, and in which bleeding was not resorted to, terminated fatally.

— During the first six months of the present year the number of deaths reported in Brooklyn was 7,938, an increase of 821 over the mortality in the corresponding period of 1886. The number of deaths from phthisis was 1,042, from pneumonia, 838, and from diphtheria, 394.

— The British ship *Arklow*, which arrived at Quarantine July 26th, after a passage of forty-four days from Rio de Janeiro, was found to have four cases of small-pox on board, the steward, two seamen, and a passenger. During the voyage three children had died of the disease, and were buried at sea. The steamship *Hipparchus*, which arrived on the 27th, from the same port, also had small-pox on board. The disease broke out soon after the vessel left Rio de Janeiro, and three passengers whose ages ranged from five to fifteen years, died during the voyage. Four other children suffering from it were removed to the small-pox hospital on North Brother's Island on the arrival of the ship at Quarantine.

— The Board of Health has adopted some new rules in regard to the work of sanitary inspectors in its service, and among them is one which requires that they must devote seven hours a day to the work except on Saturdays, Sundays and legal holidays. The working-hours are from 9 A. M., to 4 P. M., and during this time no private practice can be attended to. On Saturdays the hours of service are reduced to three. When not otherwise employed, they will be expected to make house-to-house visits among the tenements, and each inspector will be held responsible for the sanitary condition of his district; so that the special work of the Board of Health's summer corps of physicians will be maintained to a considerable extent throughout the year.

— The 22d Regiment, which went on duty at the State Camp at Peekskill, July 28th, introduced an innovation by marching the greater part of the distance from New York to the camp. They bivouacked over night on the road.

Miscellany.

TOMMASI-CRUDELI ON MALARIA.

The *Lancet*, July 9th, contains a review of the elaborate "note" recently submitted by Dr. Tommasi-Crudeli to the Royal Academy of the Lincei, entitled, "Stato attuale delle nostre Conoscenze sulle Natura della Malaria e sulla Bonifica dei Passi Malarici" ("On the present State of our Knowledge as to the Nature of Malaria, and as to the Reclamation of Malarious Countries.") The paper is a reply to the author's many critics, and his fair and courteous tone is quite as remarkable as the trenchant force of his dialectic. Without entering into the arguments with which he seeks to remove objections, or to add confirmation to his position, it appears that he has shown reasonable cause for adhering to the conclusions set forth in his now well-known treatise on the "Climate of Rome." As a working theory of the origin of malaria and its remedy, his doctrine still holds the field, while he can claim the independent investigations of pathologists like Mosso of Turin, as yet further reinforcing that doctrine. The concluding section of his paper refers to the treatment — the prophylaxis, rather — to be adopted in malarious countries, and he still holds to his belief in the preventive utility of arsenic, as "augmenting the mean resistance of the human organism to the invasion of the malarious ferment." Often enough he confesses this end is not obtained because in many cases the "specific resistance" has already sunk below the "mean resistance" either through defective or deleterious alimentation, or through long-continued depression, moral as well as vital, or through previous malarious attacks. Dr. Ricchi, medical supervisor of the South Italian Railways, and now of the Adriatic network, has, at the instance of Tommasi-Crudeli, set himself for some time to obviate these adverse conditions; and to aid the preventive virtue of the arsenic, he has prepared an aliment

which has been found materially to answer that end. It consists of a powder, impalpable, soluble in water, in coffee, in broth, and such like, prepared with the "sterilized" and desiccated blood of calves, and now known to commerce under the name of "Trefusia." The composition, quite accessible to the very poor, "has served," says Tommasi-Crudeli, "to render resistant to malaria, those whose organisms, already deteriorated, were not susceptible of protection by the arsenical treatment alone." He further reiterates his confidence in the decoction of lemon as a prophylactic and even as a remedy, in cases in which quinine and arsenic have failed. In testimony of this he adduces, the experience of Professor Colasanti and of Drs. Taussig and Ferraresi of Rome, and of Dr. Shakspeare of Philadelphia, all of whom have noticed the efficacy of the decoction in every stage of malarious disease.

Correspondence.

TEMPORA MUTANTUR.

MR. EDITOR,— The following examples of what in their time were deemed pernicious tamperings with food, and such as should be put down by the strong arm of the law, have I think, a certain interest as showing the changes in opinion wrought by time and increased knowledge.

Yours very truly, BENNETT F. DAVENPORT, M.D.

YEAST.—"About the end of the 17th century, the bakers of Paris began to substitute yeast for leaven. The practice was discovered and exclaimed against. The faculty of medicine in 1688, declared it prejudicial to the health, and many years elapsed before bakers were able to convince the public that bread raised by means of yeast is better than that fermented by leaven."— *Dr. T. Thompson's Chemistry of Organic Bodies*, Vegetables, p. 1029.

HOPS.—"They were at first considered a dangerous thing as most good things have been, and the planting of them was forbidden in the reign of Henry VI. In 1530, Henry VIII issued an order forbidding the servants of his household to add hops to his beer. Later than this the common council of London, petitioned Parliament against the use of hops, "in regard that they would spoil the taste of drinks, and endanger the people."— Page 220 of *Dr. E. Lankester's Lecture on Food, delivered at South Kensington Museum.*

EXCESSIVE SUMMER HEAT THE EXCITING CAUSE OF TUBERCULOSIS.

EVERGREEN, BALTIMORE COUNTY, MD., July 29, 1887.

MR. EDITOR,—It has long been a theory of mine, supported by facts too numerous to narrate, that excessive summer heat is the active producing cause of tuberculous phthisis pulmonaris, including of course, tubercle in whatever other structures or tissues it may be found, since it has been laid down as a law to which there is but one exception, that is, whenever tubercles exist in any part of the body, they may always be found in the lungs. The tubercular meningitis of childhood, characterized by the "*tâche meningite*" of Chomel and other well-known signs, furnishes in some instances the only exception to the universality of the foregoing law.

That heat plays the leading part in the etiology of tubercular phthisis, there is ample proof in the fact that true acute consumption, a disease lasting from fifteen to thirty days at most, from its commencement to the always fatal termination, occurs during or immediately following a heated term of greater or less duration. In the last fifty years, I have seen thirteen cases, the average duration of which was eighteen (18) days. In a majority of them the first sign noticed was anhelation from exercise or slight exertion of any sort. To the ear and hands the signs were negative, nothing being heard but an occasional sibilant or sonorous râle. In these cases hundreds of tubercles are deposited in every lobule of both lungs, no single part of the pulmonary parenchyma escaping. But, as a rule, when the nervous system is depressed by heat, tubercles are deposited most generally at the summit of one or both lungs. There they remain dormant until cold weather sets in, when the patient begins to cough, or in one out of five cases he may raise a little blood, which symptoms are noted as the beginning of the attack, when, in fact, the seed, giving rise to these symptoms, had lain dormant there ever since the heated term of the previous summer. And, therefore, the best way for those predisposed, through heredity or otherwise, to escape phthisis, is to avoid as far as practicable exposure to excessive heat.

Yours very truly, TH. H. BUCKLER, M.D.

AN "M.D." IN NINE MONTHS.

DENVER, COL., July 26, 1887.

MR. EDITOR,—In the "news" column of a recent number of the *Medical Record*, I read:—"The Medical Department of the University of ——— held its thirty-fourth annual commencement at ——— on July 15th. Fifty-three candidates received degrees."

Of the fifty-three candidates I am acquainted with one, and with his preparatory training; and, because it seems to me that the Medical Department referred to, is lax in its requirements, and not intending in any way to reflect upon the young man in question, whose zeal to become an M.D., may, perhaps, be commended, I give his history:

On the 7th of October, 1886, Mr. X, Matriculated at the Medical Department of the University of Denver. His previous training had been as a clerk in a drug store, and he possessed a certificate from a board of examiners authorizing him to practice pharmacy in the District of Columbia.

He attended the full course of lectures for the Session of 1886–87, at the Denver University; applied for examination in chemistry and materia medica, which he was permitted to do because of his training in pharmacy, and passed in these branches.

About the 25th of March, 1887, armed with a card stating that he had attended *one* lecture course, and a certificate of having passed a satisfactory examination in both materia medica and chemistry, he went East to attend the lecture course at the University of———, where he was graduated on July 15th. That is, starting upon his medical studies on the 7th of October, 1886 — on the 15th of July following he was born into the noble profession of medicine, and was recommended by the University, whose diploma he bears, to the public as one qualified to practice medicine.

Let me say right here, that this University is not a Western one, which, urged on by a desire to have a list of graduates and a body of Alumni, is willing to hasten on its labors; but it has already celebrated its thirty-fourth commencement. It is situated amongst the hills of New England, and it numbers among its Faculty men of reputation in the profession.

In these days when a suitable training in medicine is taken to mean the expenditure of years in preparation; when the profession are urging a system of legislative protection and State Boards are being organized on all hands; when ambitious students are not content with the advantages offered in this country, but must seek a foreign experience — surely no one will contend that a nine months training is adequate to the demand.

It does not seem to me that any responsibility can attach to the University of Denver in the case here cited. The young man had attended *one* full lecture course and was entitled to a certificate to that effect.

Protection to the people must come, and should be demanded, from those giving diplomas.

The University that granted this diploma professes to require for graduates (Medical Education and Medical Colleges in the United States and Canada, 1765–1885. Edited by the Illinois State Board of Health, p. 121): —

(1) Twenty-one years of age; (2) three years study; (3) two full courses of lectures in different years, of twenty weeks each; (4) good moral character; (5) satisfactory examination before the Faculty and State Medical Board of Examiners.

It is also stated that the lecture-course begins the first Thursday in March and continues twenty weeks.

Certainly, twenty weeks is none too long for a lecture-course, and it should not be abridged, as in the present case, four weeks, and still be counted as a full course.

To sum up the whole matter, the reason for my writing this communication is to call attention to a system that I think is faulty, objectionable, and which, in justice to the profession and the public, should be corrected. I have used the case cited simply as a caption to my article. I have known others, occurring at the same University, of a similar nature, though not quite so aggravated in degree. But if the system employed is pursued, there is no reason why instances like this one should not be multiplied indefinitely. Then any drug clerk in the country or any office boy to a reputable physician, can start upon a course of lectures at the Denver University, or at the Albany Medical College, or at the Long Island College Hospital, or at the Bellevue Hospital Medical College, or at a score of other medical colleges in this country, and after taking the regular winter course of lectures, he can go to the University of ——— and in nine months from the time of beginning his studies or ten months at the outside, he can come forth a full fledged M.D.

Instead of besieging legislative halls for legal enactments, let us first seek protection from those in our own ranks. Very truly yours, SAMUEL A. FISK, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 23, 1887.

Deaths reported 1,507: under five years of age 742; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 511, consumption 122, lung diseases 48, diarrhœal diseases 422, whooping-cough nine, measles 12, cerebro-spinal meningitis 12, diphtheria and croup 12, typhoid fever 18, malarial fever 11, puerperal fever nine, scarlet fever six. From cerebro-spinal meningitis, District of Columbia and Milwaukee three each, Lowell two, Pittsburgh, Somerville, Holyoke and Taunton, one each. From measles, Boston four, Pittsburgh three, Baltimore two, District of Columbia, Lowell and New Bedford one each. From malarial fever, New Orleans four, Baltimore, District of Columbia and Nashville two each, Charleston one. From whooping-cough, Boston, six, Baltimore two, Nashville one. From puerperal fever, Pittsburgh seven, Nashville two. From scarlet fever, Pittsburgh four, Baltimore two.

In the 20 cities and greater towns of Massachusetts, with a population of 1,034,088 (population of the State 1,941,465) the total death-rate for the week was 27.41 against 26.37 and 27.12 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending July 2d, the death-rate was 19.6. Deaths reported 3,475: infants under one year of age 1,007; diarrhœa 267, measles 152, whooping-cough 149, scarlet fever 54, fever 27, diphtheria 22.

The death-rates ranged from 11.4 in Nottingham to 32.1 in Preston; Birmingham 17.9; Blackburn 23.2; Bradford 14.9; Hull 15.6; Leeds 19.7; Leicester 21.5; Liverpool 22.2; London 19.9; Manchester 24.0; Sheffield 19.3; Sunderland 13.3.

In Edinburgh 18.6; Glasgow 17.8; Dublin 26.6.

The meteorological record for the week ending July 23, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 23, 1887, TO JULY 29, 1887.

MAGRUDER, D. L., colonel and surgeon. Granted leave of absence for one month, to take effect on or about August 10, 1887. S. O. 170, A. G. O., July 25, 1887.

Par. 13 S. O. 167, A. G. O., July 21, 1887, assigns Lieutenant Colonel A. Heger, surgeon, to duty as member of Army Retiring Board, convened at Governor's Island, New York Harbor, N. Y., vice Colonel Charles Sutherland, surgeon, hereby relieved.

CALDWELL, D. G., major and surgeon. Order relieving him from duty at Fort D. A. Russell, Wyo., and assigning him to duty at Fort Assinniboine, Mont., is revoked. S. O. 168, A. G. O., July 22, 1887.

CLEARY, P. J. A., major and surgeon. Ordered to Fort Assinniboine, Mont., instead of Fort D. A. Russell, Wyo. S. O. 168, A. G. O., July 22, 1887.

COWDREY, S. G., captain and assistant surgeon. Granted one month's leave of absence to take effect on or about July 24th. S. O. 79, Department of Texas, July 13, 1887.

BURTON, H. G., captain and assistant surgeon. Sick leave of absence extended three months. S. O. 171, A. G. O., July 26, 1887.

GARDNER, E. T., captain and assistant surgeon. Ordered for duty at Fort Reno, Ind. Ter. S. O. 170, A. G. O., July 25, 1887.

BLACK, C. S., first lieutenant and assistant surgeon. Ordered for duty as Post-Surgeon, Fort Bliss, Tex., during the absence on leave, of Capt. S. G. Cowdrey, assistant surgeon. S. O. 79, Department of Texas, July 13, 1887.

MCCAW, W. D., first lieutenant and assistant surgeon. Ordered for temporary duty at Fort Riley, Kans. S. O. 78, Department of Missouri, July 25, 1887.

OBITUARY.

OSCAR FITZWILLIAM FASSETT, M.D.

Dr. O. F. Fassett, of St. Albans, Vt., died July 22, after a lingering illness from cancer. He was born at Enosburg Falls, February 28, 1827. After passing through the public schools of his native village and the academy at Bakersfield, he chose the medical profession, and graduated with high honors at the Vermont Medical College at Woodstock in 1851. He subsequently took a course of medical studies in New York City, and commenced to practice medicine at East Berkshire, where he remained twelve years. He came to St. Albans in 1865, and here he has since continued in the discharge of his professional duties. He was eminent in his profession, and, as a physician and a gentleman, his reputation stood deservedly high throughout the State. He was the President of the Vermont Medical Society for two years, and took a deep interest in the organization.

BOOKS AND PAMPHLETS RECEIVED.

Massachusetts College of Pharmacy. Twenty-first Annual Catalogue, 1887–88.

Syphilis. By Jonathan Hutchinson, F.R.S., LL.D. With eight chromo lithographs. (Clinical Manuals for Practitioners and Students of Medicine.) Philadelphia: Lea, Brothers & Co.

Annual Announcement of Trinity Medical School, Toronto. Session 1887–8.

Recent Advances in Preventive Medicine. By George H. Rohé, M.D., of Baltimore, Md. Chicago, 1887. (Reprint.)

Thirty-Second Annual Report upon the Births, Marriages, and Deaths in the City of Providence, for the Year 1886. By Edwin M. Snow, M.D., City Registrar.

Duty of the State in Public Health. By F. B. Stephenson, A.M., M.D., United States Navy, Member Titulaire de la Soc é d'Anthropologie de Paris. 1887. (Reprint.)

A Unique Case of Bi-Lateral Athetosis. By C. H. Hughes, M.D., St. Louis, Neurologist on the Staff of St. Louis Protestant Hospital, Lecturer on Nervous Diseases, St. Louis Medical College, etc. 1887. (Reprint.)

On the Pathology and Treatment of Gonorrhœa and Spermatorrhœa. By J. L. Milton, Senior Surgeon to St. John's Hospital for Diseases of the Skin, London. Octavo, 484 pages. Illustrated. New York: Wm. Wood & Co.

The Curability of Insanity and the Individualized Treatment of the Insane. By John S. Butler, M.D., Hartford, Conn., Late Physician and Superintendent of the Connecticut Retreat for the Insane, etc. New York and London: G. P. Putnam's Sons. 1887.

Insanity and Oöphorectomy. By William M. Leszynsky, M.D., Instructor in Mental and Nervous Diseases at the Post-Graduate Medical School and Hospital, Attending Physician in the Nervous Department of the Demilt Dispensary, etc. 1887. (Reprint.)

A Third Contribution to the Study of Localized Cerebral Lesions. By E. C. Seguin, M.D., Clinical Professor of Diseases of the Mind and Nervous System in College of Physicians and Surgeons, New York, etc. New York: J. H. Vail & Co. 1887. (Reprint.)

The Mineral Waters of Vichy and the Diseases in which they are indicated. Followed by a Sketch of some of the Principal Excursions in the Environs. With Two Colored Maps. By Dr. C. E. Cormack, Laureate of the Faculty of Medicine of Paris, etc. London: J. & A. Churchill. 1887.

Heredity in Tuberculosis. President's Address, At the Meeting of the American Climatological Association, May 31, 1887. By Frank Donaldson, M.D., Clinical Professor Throat and Chest, University of Maryland, Fellow of American Laryngological Association, etc. Baltimore, Md., 1887. (Reprint.)

Importance and Value of Experimental Research. Doctorate Address Delivered at the Graduating Exercises of the College of Physicians and Surgeons, Chicago, Ill., February 21, 1887. By N. Senn, M.D., Milwaukee, Wis., Professor of Principles and Practice of Surgery and Clinical Surgery. 1887. (Reprint.)

A System of Gynecology by American Authors. Edited by Matthew D. Mann, A.M., M.D., Professor of Obstetrics and Gynecology in the Medical Department of the University of Buffalo, N. Y. Volume I. Illustrated with Three Colored Plates and 201 Engravings on Wood. Philadelphia: Lea Brothers & Co. 1887.

Three Lectures delivered at the Hospital for Sick Children, Great Ormond Street. By Robert J. Lee, M.D., F.R.C.P. Lectures I and II. On the Transmission of Syphilis; with Cases arranged to illustrate the Relations between the various Symptoms of Hereditary Syphilis in Children and the Parental History. Lecture III. On the earliest Record of Whooping-Cough. London: Baillière, Tindall & Cox. 1886.

Original Articles.

CARLSBAD.

BY HORATIO R. BIGELOW, M.D.

It appears at first sight a work of supererogation to add to that which is already of record, touching upon Carlsbad and upon disordered livers generally. Yet it seems to me that this little Bohemian village is far too little appreciated, and what has been said about it, and what has been written in its praise, have not exhausted the subject in any perceptible degree; they have only whetted the appetite, as it were, for more. I do not know to what extent I may impose upon the forbearance of the editor of this journal, neither can I guage the measure of charity possessed by its readers. But I must put both to the test, if I would do even the most limited justice to the subject. It smacks a little bit of the "meeting-house," and the "Cotton Mather" school, that I should divide my article into several heads, but I come righteously by certain characteristics of the Puritan, and the processes of heredity are overmastering. With this much as preface, I submit the following points for discussion:

I. Why I came to Carlsbad.

II. The springs of Carlsbad.

III. Diseases in which indicated. Cardialgia, ulcus ventriculi, catarrhal conditions of the stomach, dilatation of the stomach, chronic constipation, chronic intestinal catarrh, congestion of the liver, fatty liver, cirrhosis of the liver (first stage), polycholia, gallstones, splenic tumors, gravel, catarrh of the bladder, prostatic hypertrophy, anæmia, gout, adiposis, diabetes (?), etc. Some dermatological and gynæcological diseases.

IV. Contra-indications.

V. Modus operandi of the cure.

VI. Hygienic and dietic regulations.

VII. The baths.

VIII. The situation of Carlsbad; its environs, climate and approaches.

IX. Expenses, pensions, hotels, etc.

I. WHY I CAME TO CARLSBAD.

Upon the recommendation of Dr. Sänger, of Leipsic, who diagnosed a considerable enlargement of the liver in a member of my family, with some catarrhal condition of the gall ducts, conjoined to some old inflammatory deposits in the peritoneal cavity as a result of para and peri-metritis. The patient's complexion at all times more or less icterus, was at times, especially during the menstrual period, markedly icterode. The face was spotted here and there with brown plaques, always more pronounced on the forehead. To palpation the liver was hard and resisting. The lower lobe extended nearly three fingers breadth to the left of the middle line, and downward to within two fingers breadth of the crest of the ilium. There was one exquisitely sensitive spot in the middle line just above the umbilicus. There was faulty digestion, and a long train of aches and pains, depending upon many causes which I need not detail here. We left Leipsic at noon, March 15th, and as, during this season the regular through trains do not run, we did not arrive in Carlsbad until midnight, and then were greeted with a snow-storm which continued persistently for three or four days.

II. THE SPRINGS OF CARLSBAD.

Name.	Temperature. R.	F.	Name.	Temperature. R.	F.
1. The Sprudel	59.5°	166°	10. Schlossbrunn	43.5°	126°

9. Mühlbrunn	45°	133°			

The Commissioners of the Government after a series of very careful analyses, demonstrated 41-42 of solid constituents in one pound (16 ounces) of Carlsbad water. Prof. Ragsky, in 1863, made the following analysis:

Solid Constituents Contained in 16 Fluid Ounces.	Sprudel.	Mühlbrunn.	Schlossbrunn.
Sulphate of potash	1.2564	1.7172	1.4645
Sulphate of soda	18.2160	17.9610	17.2455
Chloride of sodium	7.9156	7.8690	7.5282
Carbonate of soda	10.4593	10.8679	9.5620
Carbonate of lime	2.2870	2.0236	3.0658
Carbonate of magnesia	0.3532	0.2641	0.3870
Carbonate of protoxide of iron	0.0215	0.0230	0.0176
Carbonate of protoxide of manganese	0.0046	0.0053	0.0053
Carbonate of strontia	0.0061	0.0069	0.0046
Phosphate of aluminum	0.0030	0.0025	0.0023
Phosphate of lime	0.0015	0.0016	0.0030
Fluoride of potassium	0.0276	0.0268	0.0291
Siliceous earth	0.5590	0.6190	0.7365
Total of solid constituents	41.7090	41.3870	40.1523
Free carbonate acid in grains,	5.8670	7.3260	10.2940
Free carbonate acid in cubic inches.	11.8820	14.8370	20.6200

and Ludwig, of Vienna, in 1879, published this analysis made by himself:

10,000 Grammes of the Water Contain.	Sprudel.	Mühlbrunn.	Schlossbrunn.
Carbonate of protoxide of iron	0.030	0.028	0.001
Carbonate of protoxide of manganese	0.002	traces	traces
Carbonate of magnesia	1.665	1.613	1.615
Carbonate of lime	3.214	3.266	3.357
Carbonate of soda	12.980	12.700	12.279
Carbonate of strontia	0.004	0.004	0.004
Carbonate of lithia	0.123	0.118	0.136
Sulphate of potash	0.862	1.188	1.030
Sulphate of soda	24.053	23.941	23.158
Chloride of sodium	10.418	10.288	10.047
Fluoride of potassium	0.051	0.046	0.046
Borate of soda	0.040	0.029	0.039
Phosphate of lime	0.007	0.009	0.004
Siliceous earth	0.004	0.005	0.005
Silicic acid — anhydrate	0.715	0.735	0.703
Calcium, rubidium, bromine, iodine, arsenic, antimony, zinc, selen, thallium, formic acid	traces	traces	traces
Total of solid constituents	55.168	54.730	53.304
Carbonic acid, half combined	7.761	7.672	7.593
Carbonic acid, free	1.898	5.169	5.822

Small quantities of iodide of sodium, bromide of sodium, lithia, boracic acid, rubidium and calcium, are also found. All the surface waters of the Carlsbad region, including the river Tepl, penetrate the granite rocks and soil to great depths. They do this the more easily, owing to the disintegrated character of the granite formation. Carlsbad lies in what must have been a volcanic region. The geological formations, and the peculiar conformation of the land all point to this conclusion. It would require no imaginative deduction to relegate the present site of this town to the crater of an extinct volcano, or if not so, we should not be far amiss in asserting that it rested upon volcanic debris, thrown down by a volcano which has

been extinct for ages. In its downward course this surface water becomes impregnated with the granite constituents, which Göttl has shown to be soda, lime, potash, siliceous earth, aluminum, magnesia, iron, manganese, arsenic, chlorine, flourine, sulphur, sulphuric and phosphoric acid. From the soil, it becomes heavily charged with carbonic acid. Owing to the action of this acid, and a counter atmospheric pressure, it dissolves, both by chemical and physical action, the solid mineral and extracts the salts, which are held in solution by carbonic acid gas. Knowing that the temperature increases, as we go down into the earth, and having learned exactly, in just what ratio such increase occurs, it is not difficult to locate the depth of the basin which supplies the springs, beneath the earth's surface. This is estimated to be 8000 feet. As all of the Carlsbad springs contain almost identically the same ingredients, they must have one reservoir in common. The difference in temperature of course is due to the length of time taken to reach the surface. The spring which takes the most direct route, will manifest itself first, and will be the hottest. The heat which the surface waters draw from the strata in their descent, sets free the carbonic acid gas, and it is this strongly propelling force which forces them back as spouting springs. The whole face of the country, the nature of the springs, the intermittent character of the supply, and the influence of earthquakes, and active volcanoes at a great distance upon the amount of the water, seem to point to volcanic origin, beyond all question of a reasonable doubt. Eidmann and Göttl found electro-magnetic currents (negative) in some of the warmer springs — a fact without much significance, when we remember the constituents of the water. The bicarbonates, which are held in solution by the carbonic acid, become precipitated by exposure to the air, and encrust, with beautiful effect, everything with which they come in contact. The solid constituents of each spring are *about* the same. They all belong to the saline alkaline springs, and are like the "Glauber's salt waters" of Stubnya and Beitrich. Sulphate of soda, carbonate of soda, and chloride of sodium, are the chief ingredients. These of themselves are not wonderful as remedial agents. Any one can make an artificial solution at home, or can take the bottled imported water, or a dose of glaubers salt, or Dr. Kinnicutt's formula of 50 parts of sulphate of soda, 20 parts of bicarbonate of soda, and 10 parts of chloride of sodium, or sulphate of soda with sulphate of magnesia in Apollinaris water, as recommended by Jacobi, but the "Carlsbad Kur" will not follow any such line of treatment. It is not the glauber's alone, it is not the carbonic acid gas alone, it is not the temperature alone, it is not the diet and the exercise alone, but it is a combination of all under the direction of an intelligent physician which effects the results that have made Carlsbad so celebrated. A patient who is so determined upon getting well, as to make the journey here, will, ten chances to one, more religiously conform himself to doctor's orders than he ever did at home. There is, too, potentiality for good, in these waters taken at their natural temperature, with their proper admixture of carbonic acid. A potentiality which no imitation can possibly obtain, and which, even the bottled waters will fail to accomplish. Chemical combinations become changed, not only in their molecular formation, but in their therapeutic action, by the action of heat. Clinical evidence of this can be had here daily. Proof also is not wanting that cases in America, under the most intelligent handling, and favorable circumstances, failed to respond to a therapeutical system based upon a knowledge of the ingredients of the Carlsbad waters, to rebound, as if by magic, first to convalescence, and then to restored health, after a four or six weeks' course at Carlsbad. I have heard that at attempt will be made to establish a "Karlsbad Kur" at Atlantic City. I predict its failure. It is simply impossible to reproduce the waters.

III. DISEASES IN WHICH THESE WATERS ARE EFFICACIOUS.

Diabetes. There lately appeared in an Hungarian medical journal (an abstract of which is also to be found in a late number of the *London Lancet*) an article by a certain doctor in Karlsbad. He avers that he has treated over two thousand cases of diabetes successfully by using saccharine. Now this same doctor has only been in Karlsbad for two years, and during this time there have not been more than eight hundred to one thousand diabetic patients here. Dr. Grünberger or Dr. London, who have the best practices here, rarely see more than forty such patients during a year. Another point: The first intimation of saccharine that the author of this remarkable paper had, came from a physician whom he had summoned to attend his daughter, who was ill, and he it was who recommended saccharine to disguise the taste of quinine. There are doctors and doctors, and let him who comes to Karlsbad beware. To make both ends meet, the struggling wayfarer must bring himself into notice in some way, either by fair means or foul. I should consider any one fortunate who counted himself a patient of Dr. Grünberger, or Dr. London, or Dr. Kraus, or Dr. Neubauer. To the former I am under obligations for the most successful and intelligent handling of the patient, whose illness brought me to Carlsbad. His quick grasp of the situation, the accurate diagnosis born of an almost unequalled experience, his kind but firm demeanor stamp him at once as the courtly gentleman and reliable physician. Now, I do not quite see what effect Carlsbad waters have upon the sugar diathesis, and I am sure that Dr. Grünberger is also somewhat sceptical in this direction. Dr. Kraus does not share in this scepticism, for he writes: "The influence of Carlsbad mineral waters on diabetes is highly beneficial, according to the unanimous opinion of medical men in general, and of those practising in Carlsbad in particular, and is based on the experience of the last fifty years. In every case of diabetes, even of the greatest severity, a marked improvement in the desolate condition begins after a few day's time. . . . The question whether diabetes may be entirely cured by the Carlsbad mineral waters, or by some other remedies, remains undecided at present, and according to the experience hitherto attained, is not likely to be answered in the affirmative." He then cites two cases in his own practice, which he considered "as perfectly cured." Hufeland called Carlsbad "the great hospital for diabetes." Braun and Seegen both report cases which were alleviated. Leichtenstern says that the so-called cures are due to strict attention to anti-diabetic diet.

Many experiments have been made (P. Gultmann, Riess & Külz), showing that the "use of the Carlsbad

water has not the least power of diminishing the amount of sugar in the urine in diabetes mellitus." I see no reason to believe that the waters themselves can have the least possible influence in controlling the amount of sugar in the urine. We have no analogous data to support such a theory, and those who defend it, must know just how the change takes place. Carlsbad water *plus* Carlsbad rule will alleviate all but the very bad cases, but Carlsbad water *minus* restraint is *nil*. Still I am convinced that the very cases that do badly at home, that grow worse instead of better each month, would respond more vigorously to common sense rules in Carlsbad. The reasons are subjective and objective. The patient has faith that the long journey and the celebrated Carlsbad waters will benefit him, and he not only determines to do all in his power to profit by the experience, but he puts his system in the best condition possible for such an experiment. Then he obeys the doctor's strict injunctions more faithfully here than was his wont at home. He lives in the sunlight, he keeps good hours, his mind is free from strain, and his diet is regulated to a nicety. It is pure nonsense to talk about the curative value of saccharine. It is a useful adjuvant. It takes the place of sugar and supplies a want, but more than this *it is not*. Carlsbad is unquestionably a good place for diabetic patients because they learn to *obey*, and just in proportion as they faithfully observe the precepts taught, will their measure of well-being follow.

Adiposis. When I came to Carlsbad, I weighed between 186 and 190 pounds (American). As I am only five feet, six-and-one-half inches tall, this was too portly, even for a London alderman. Dr. Grünberger thought there might be a tendency to fatty degeneration of the heart, and advised the *Kur*. I began with two glasses (March 16th) of Marktbrunnen daily, to which was added, on March 20th, one glass of Mühlbrunn. This was never increased during the eight weeks of my cure. The water was sipped gradually; then, after an interval of fifteen minutes, the second glass was taken, and so the third. After that, a walk of from one to two hours, and then breakfast. A cup of tea or coffee (with milk and sugar), two rusks, and two soft-boiled eggs, then a climb of two or three hours, and home to dinner — a piece of rare meat and one vegetable, with an occasional glass of Hungarian wine. Then another long walk, followed by supper at seven, consisting of tea, rusks, and cold meats. I took a few warm and vapor baths, especially when in Berlin, to which city I was called upon business, being absent ten days. While away, I kept up my diet rules most strictly, but not being able to exercise as vigorously, I indulged somewhat in Turkish baths. Latterly, I have given up coffee, and take no milk in my tea. At first, the waters caused a natural, but rather active movement from the bowels; then, for two or three weeks, the discharges were more frequent (twice, and sometimes three times per day), and then came an interval of constipation. My weight fell as follows:

March 20th	84.200 kilogrammes	184.13 Pounds (American).	
March 27th	83.000 "	182.0 "	
April 4th	81.700 "	179.4 "	
April 10th	78.700 "	172.7 "	
April 17th	77.500 "	169.13 "	
April 24th	75.250 "	164.14 "	
April 27th	74.240 "	162.9 "	
April 30th	73.750 "	161.9 "	

I now weigh (May 26th) about 155 pounds with winter flannels. My weight, naked, at the Cur Haus bath-rooms was, on May 23d, 67 kilogrammes = 134 German pounds, or 148 American pounds. I exercise about three or four hours daily, and observe a rigorous self-denial in matters of diet. It will be seen that from March 4th to March 10th, I lost nearly a pound *per diem*, but during this time I am sure that I walked between twenty and twenty-five miles daily. At no time have I felt unpleasantly. At times, the more especially after hot baths, and sometimes in the early morning, I fancied that I was a little groggy in the legs. I have not been as sprightly upon setting out upon my walk as I might be; still these were natural symptoms, and soon wore off. It seems to me that I am better, stronger, and more free from headaches than I have been for years. I can make the longest and most trying walks without undue fatigue, and my mind grasps an idea more quickly, and can unravel a theory more satisfactorily than formerly. The share of the waters in this rôle must be considered as a small one. The slight purgative effect assists digestion, and, in this way, may contribute in some small way to the general result. The absorbents are stimulated, and the fatty deposits diminished, more, I think, by reason of the high temperature of the water. Clinicians hold that, absorbed by the blood, the waters remove the fat in subcutaneous areolar tissue and in other organs, but they do not give us any physiological proof of this. One of the latest works on this subject in German advocates most strongly the internal use of hot water as a means of reducing adipose. The salts may act indirectly by depriving the excess of adipose of its rich and elaborate nutrition, since the use of Carlsbad waters not only lessens the richness of the blood-supply, but it also changes the whole character of absorption.

Diseases of the Liver. (See Frerichs' work, and those of Oppolzer, Bamberger, Ducheck, and Fiedler, etc.) In *passive congestion* caused by emphysema, stagnation in the mesenteric vein, constipation, and other functional disorders of the abdominal viscera, *fatty liver*, the first stage of *cirrhotic liver*, *polycholia*, *catarrhal jaundice*, and, according to Leichtenstern, in *chronic gastro-intestinal hyperæmia and catarrh*, dependent on anatomical changes in the liver, these waters, by increasing peristaltic action, and "facilitating the flow of blood through the liver," are of the most pronounced service. "Their curative effects in catarrhal jaundice depend on the favorable influence they exert on catarrh of the duodenum, and removal of obstacles to the flow of bile caused by the swollen mucous membrane. The waters have no specific effect upon the bile itself, but merely render it thinner and more abundant, and increase its flow, as any other water would do." (Page.) But these waters certainly act in another way. *They change the condition of the blood*, regulating and increasing both venous and arterial circulation, and relieving the overweighted mesenteric vein. The changed blood-supply sets up altered nutrition, and this effect is intensified by the changes going on in the mucous membrane of the stomach and of the intestinal tract. Oppolzer relates the complete cure, in an Austrian officer of cavalry, of supposed carcinomatous tumor of the liver by the use of these waters.

Gall-stones. Page says (*Medical Record*, October 30, 1886): "According to Leichtenstern, it has been often proved 'that saline soda-waters, in public and private practice, as well as at renowned watering-

places, assist in the removal of gall-stones.' By some, this is attributed to the dissolving power of the water, which is supposed to saponify the cholesterine, so that the stone breaks up into detritus, though supposed alkalescence of the bile produced by the waters has not been proved. Moreover, those stones which have a covering of carbonate of lime cannot be thus affected. Seegen states that the method of cure in these cases is not known, and favors the idea of the waters being preventive, rather than curative, and agrees with Leichtenstern in the opinion that, owing to the increased flow and pressure of bile, and increased activity of the gall-bladder, due to general reflex peristalsis, a cure is effected by expulsion of the stones, instead of their being dissolved."

Dr. Kraus says: "There is no decided proof whatever to support the opinion that the beneficial results brought about by the use of the Carlsbad waters in these cases are due to any dissolving action on their part. I have repeatedly, and for some considerable time, exposed gall-stones to the action of hot Sprudel water (60° R. = 167° F.) without noticing any mechanical changes whatever; besides, it is, *a priori*, quite incomprehensible how the mineral water should act in a direct way on the concretions formed in the gall-bladder or the biliary ducts. On the other hand, the possibility of the bile itself acting in a destructive manner on the concretions, after becoming alkaline to a certain extent, cannot be denied altogether; at least, it is certain that we frequently meet with corroded concretions of a porous construction, and sometimes, even crumbled to pieces, in patients who have been drinking the waters for a considerable time. . . . At any rate, the disappearance of the stones is not due to their being dissolved, but it may safely be asserted that their elimination is caused by the mechanical action of the waters; their importance, moreover, is evidently shown by the thinner and normal condition of the bile showing itself during their use; thus the formation of fresh concretions is evidently prevented." The almost universally favorable results in these cases from drinking the waters depend upon the "flushing," as it were, of the gall-ducts, the regulation of the action of the bowels, and by restoring the bile to its normal consistency. I have seen many remarkable cases here, and have heard of scores of equal interest, all of which were entirely cured. I met, this season, a gentleman connected with the Northern Pacific Railroad, who was sent over last year by Dr. Loomis. He had suffered terribly for years. Last year, he remained seven weeks. Returned to New York, and up to April 15, 1887, he had but one attack, and that a slight one. I saw him a few days ago, just as he was arranging to return. He looked remarkably well, and told me that he did not remember when he had been in such exuberant health. Had I a patient afflicted with gall-stones, I would urge his immediate trip here, even at the cost of the greatest personal sacrifice. It pays to come. At first, the attacks of colic after taking the waters are severe and frequent, because the stones are being eliminated, and perhaps, incarcerated. Then comes a jaundice, more or less severe. In some cases, the patients grow worse and worse. They return home after four weeks, are seized with agonizing pain, pass a lot of stones, and go on to a perfect recovery.

(To be continued.)

UTERINE HÆMORRHAGE: A CONSIDERATION OF SOME OF THE LESS COMMON CAUSES AND THEIR TREATMENT.[1]

BY F. H. DAVENPORT, M.D.,
Assistant in Gynæcology, Harvard University.

HÆMORRHAGE from the uterus, whether menorrhagia or metrorhagia, may be, as regards its cause, either active or passive; that is, it may result, in the first place, from the presence of something in the cavity of the uterus which directly attracts blood, causing active congestion; or, in the second place, from obstruction to the return of the venous blood, causing passive congestion. The importance of carefully distinguishing these two forms cannot be too strongly insisted upon, inasmuch as the treatment will be radically different as one or the other cause predominates.

It may be broadly stated that active hæmorrhage is due to causes inside the uterus itself, while passive hæmorrhage is due to causes outside the organ. As an example of the first, a submucous membrane may be instanced, and of the second, pelvic cellulitis. It will be readily seen, however, that in not a few cases both classes of causes may be operative. For example, a thickening of one or both broad ligaments may so interfere with the circulation as to induce congestion of the uterine membrane, and consequent menorrhagia. The prolonged congestion may lead to proliferation of the tissues and to so-called hyperplastic endometritis, or the development of polypoid growths, which themselves may actively determine an unusual flow of blood. The general distinction may, however, be maintained, and our treatment, in the one case, should be mainly intra-uterine, and in the other, directed to conditions outside the organ. This applies, of course, only to radical treatment, for we are often driven by the alarming severity of the flow to temporarily, at least, resort to the most effectual means, regardless of the predisposing cause.

Most uterine hæmorrhages are intermittent, the periods of severe, and possibly alarming, flowing being followed by intervals of either complete cessation, or very nearly so. When the flow is at its maximum, little more can usually be done than to check it, reserving a more thorough examination to determine its cause for the interval of comparative quiescence.

It is certainly a mistake to neglect such an examination. If the hæmorrhage occurs only at the time of the menstrual period in a young girl, general hygienic and tonic treatment should be tried before resorting to a vaginal examination; but if it occurs in the intermenstrual period, whether the woman be married or single, and in any case in a married woman, its cause should be sought for by every means in our power. Too often the failure to do this in a case of beginning epithelioma, for instance, allows the favorable moment for the performance of a radical operation to slip by, and when the delayed examination is made, the disease is found to be so far advanced as to admit of only palliative treatment.

This caution applies particularly to hæmorrhages occurring between forty and fifty, or at the time the menopause is expected. Irregularities in the amount of the menstrual flow in women of that age excite little alarm, for they are considered by the women

[1] Read before the Section of Obstetrics and Gynæcology of the Suffolk District Medical Society, April 20, 1887.

themselves, and too often by the physician, as the natural accompaniment of the "change of life."

Certain statistics with regard to the comparative frequency of the various causes of uterine hæmorrhage, and the age at which they most frequently occur, will illustrate the importance of this warning. Dr. Sneguireff, of Moscow, has written a monograph on uterine hæmorrhage, in which he gives a table prepared from all the data which he could collect, which shows the following facts: By far the most frequent cause of hæmorrhage from the uterus is cancer, constituting twenty-five per cent., or a quarter of all the cases we meet with. The next most common cause is fibroid, nineteen per cent.; then metritis, ten per cent.; endometritis, eight per cent.; abortions and subinvolution, five per cent.; and twenty-two other less frequent causes, ranging from three per cent. to one per cent. each.

A second table gives the relative frequency of the different causes of uterine hæmorrhage at the different ages. From this, we see that nearly ninety per cent. of cases of hæmorrhage from cancer occur in women over thirty-five, and fifty-eight per cent. in those over forty-five; that nearly fifty per cent. of hæmorrhages from fibroids are in women over thirty-five, and twenty-five per cent. in those over forty-five, showing that nearly half of all cases of metrorrhagia that we meet occur in the years about the menopause, and are due to the two grave affections, cancer and fibroid. In striking contrast to these statistics, is the fact that less than one per cent. of such cases can be referred to the menopause as the sole cause; that is, where nothing else to account for it can be found.

Of especially grave import are irregular "flowing spells" occurring after the menopause is once established. No reluctance on the part of the patient to submitting to an examination should induce the attending physician to fail to insist upon its importance.

Another class of cases which is too often neglected is that where the menstrual flow is excessive. Many a woman is kept in a condition of enfeebled health from the monthly drain upon her system, in whose case a little care would so moderate the flow as to enable her to thoroughly recuperate in the intermenstrual period. I am convinced that there are cases, not a few, where the women are better off for not menstruating at all. They can ill afford to lose any blood, and if nature has not pointed out the true remedy by a state of amenorrhœa, any flow of blood should be looked upon as a hæmorrhage, and be treated as such. In such cases, rest in bed and frequent hot-water douches will often reduce the flow to a minimum, or stop it altogether.

On the other hand, it is often a difficult matter in cases where the menstrual flow is profuse, to decide whether it is excessive, and needs to be checked or not. I have a patient who has always flowed a great deal, using on an average thirty napkins, and passing numerous clots besides. When she was regaining her strength after an operation, I feared the drain upon her system was too much, and diminished the amount of the flow after the first three days, by ergot and hot water injections. But severe headaches, increased backache, and bearing down followed, and I became convinced that in her case this large amount was none too much. There must be a great difference in the blood-making capabilities of different women, otherwise we cannot account for so great a monthly loss of blood in one case being not only not followed by bad consequences, but even necessary to a comfortable degree of health, while a third of the amount in another woman is a severe drain, from which she does not recover in the intermenstrual period, but grows steadily weaker.

Hæmorrhage during menstruation, or menorrhagia, rarely calls for active local treatment at the time, as the amount of blood lost can usually be controlled by internal medication, rest in bed, and hot douches. Occasionally, however, the vaginal tampon is necessary. But a great deal can be accomplished by treatment during the intermenstrual period both in the way of relieving congestion by local measures, and particularly by regulating the habits and mode of life of the patient. I have several times seen severe menorrhagia in young girls who were studying too hard, and taking too little exercise, where removing them from school and from the excitements of city life, and insisting upon out-door exercise, with some ferruginous tonic has resulted in immediate diminution of the amount of blood lost. A vaginal examination is often not necessary in these cases. Where I have made one, I have usually found a small flabby anæmic uterus, cervix conical, and possibly anteflexed, and an absence of leucorrhœa. Here the bleeding seemed to be directly due to the atonic condition of the uterus.

By far the greater number of cases of hæmorrhage, both during the catamenia and in the interval, are associated with a congested, enlarged, and sensitive uterus, and there is considerable leucorrhœa when the bloody discharge ceases. Sometimes we find nothing but the above conditions on local examination, and are forced to interrogate other organs, at a distance, as heart, lungs, or kidneys, or to look for some morbid diathesis as a predisposing cause. In this connection some observations lately published in the *British Medical Journal*,[2] are of interest. In investigating some questions with regard to phthisis, Dr. Handford found confirmation of the following maxims:

First. Early or excessive menstruation is an important and common predisposing cause of phthisis.

Second. The female children of phthisical parents tend to menstruate unduly early and excessively.

In support of these views, in addition to some cases of his own, he quotes Dr. Grailly Hewitt, who says: "According to my experience, young women in whom there are signs of a tendency to, or an actual development of tubercle are very frequently the subjects of profuse menstruation, the cause being the defective and vitiated state of the blood."

It may be considered doubtful whether, as Dr. Handford states, menorrhagia is a *common* predisposing cause of phthisis, yet in view of these facts it certainly should be looked upon as a suspicious circumstance, when a child of phthisical parents flows early and excessively, and we should use all the means in our power to check it.

As a rule, the vaginal examination will reveal some definite cause for the increased congestion, and the consequent hæmorrhage, and this must be the object of our treatment. To enumerate the pathological changes which give rise to uterine congestion would be to go over pretty much the whole field of uterine disease. It may be of interest, however, to notice rather more in detail a few of the less common causes.

I have alluded above to atony of the uterus. I

[2] Article, Menstruation and Phthisis, January 22, 1887.

have occasionally found menorrhagia associated with a condition of anteflexion, usually of the neck, sometimes of both body and neck, in an anæmic woman, with flabby muscles, weak action of the heart, poor appetite and delicate digestion, and I have been rather at a loss to satisfactorily explain the logical sequence of events. I am inclined to agree with Grailly Hewitt in attributing the symptoms we find in these cases to malnutrition. He goes further than I would in considering malnutrition to be the most common cause of all uterine displacements, and their immediate results, but here I agree with him that the first factor of importance in these cases as an abnormal softening of the uterus due to too little food. When at the time of puberty the uterus develops, the body, which up to that time has been smaller than the cervix, fails to attain its proper size and remains small and flabby, while the cervix bends forward on its axis at the internal os, and in time becomes permanently fixed in a condition of anteflexion, long conical, and pointing in the axis of the vagina. In these cases the menorrhagia, which is, to be sure, often only relatively profuse, is, as has been pointed out before, due to atony, and may best be treated by general hygienic and tonic treatment. Perhaps a more common cause of uterine hæmorrhage, and one which is quite frequently overlooked, is retroflexion of the uterus, especially when bound down by adhesions. Here the interference with the circulation is more marked, so that in addition to a profuse menstrual discharge, there may be a slight but constant flow in the intermenstrual period. This often is hardly more than enough to necessitate the use of perhaps one napkin a day, and in some cases a profuse leucorrhœal discharge, at times brownish or tinged with blood, may be the only sign of congestion.

In the early stages the changes in the endometrium are very slight, but if the stasis be long continued, there may result hyperplasia of the lining membrane, which in turn becomes a secondary and even more active cause of hæmorrhage than the original displacement. If treatment, however, be directed to the condition of the endometrium, either by astringent applications or by curetting, though temporary benefit may be attained, yet the diseased condition is likely to reproduce itself as long as the organ is in its abnormal position.

Treatment to be effectual should be primarily directed to the misplacement, and as adhesions are generally present in these cases, packing the vagina regularly with glycerine cotton tampons is the method most likely to be followed by success. This form of treatment fulfils several indications. In the first place, it is in my judgment the surest and safest method of overcoming the adhesions and restoring the organ to its normal position; in the second place, it usually is effectual in controlling the hæmorrhage; and in the third place, the glycerine from its affinity for water depletes the tissues, and relieves congestion.

The following case will serve to illustrate this form of uterine hæmorrhage, and its treatment.

Mrs. S. was first seen January 25, 1886. She was twenty-five years old, married three and a half years, has had two children, the oldest two and a half, the youngest fifteen months. She nursed her children, and the first menstruation since the birth of the last child came on in July, six months previous to my seeing her. This was normal in amount. The next catamenia flow was a week over time (the delay as she thinks having been occasioned by her going in bathing on the day her menses were expected), and she flowed profusely for a week. The same thing occurred in September. In October and November there was some improvement. December 8th, the sickness returned, and from that time until I saw her, a period of six weeks, she had only short intervals of a few days respite. At times there were smart hæmorrhages, but naturally the flow was moderate, and the patient kept about most of the time. She suffered considerable pain in back and right side, and the constant drain was beginning to tell on her strength. When she was not flowing there was a good deal of leucorrhœal discharge. Bowels were usually constipated. On examination, I found an enlarged and congested cervical portion, pointing in the axis of the vagina, the uterine body behind, and apparently fixed by adhesions in a position of retroversion with slight flexion. She was then flowing considerably.

I first carefully curetted the uterus with a dull wire curette, and removed a small amount of hyperplastic mucous membrane, and then tamponed the vagina tightly with glycerine cotton. This failed to control the hæmorrhage completely, some blood finding its way through the packing by the next day, but the amount was decidedly diminished. I removed the tampon the second day, and this time added a uterine plug of iron cotton to the vagina packing, which was successful in checking the hæmorrhage. Hoping that the curetting would be all that was immediately necessary, and thinking it would be wiser to delay the reposition of the uterus until the patient was stronger, no further local treatment was given, and, in fact, there was no return of the hæmorrhage for three weeks.

It then came on, and before I was called she had lost a great deal of blood. As this corresponded to the time of the catamenia, efforts were at first directed towards modifying, rather than completely checking the flow. Ergot, ergot and hamamelis, and gallic acid were tried, and hot-water injections were given. The effect, however, was not what was desired, and a firm tampon of both uterus and vagina was resorted to, with good result. As it seemed evident that the ultimate cause was to be found in the displacement of the uterus, this time the systematic packing of the vagina was kept up during the intermenstrual period, and the uterus was already in a much better position by the time the next menstruation was expected. This, though more profuse than was natural, did not call for any interference, and before the next sickness the uterus was in normal position, and the menstruation was of the ordinary amount. There has been no trouble since.

There is a form of hæmorrhage which is not very common, coming on in the early months of pregnancy. The history of the few cases I have seen is this: Somewhere from the second to the fourth month, usually without warning, there is a sudden gush of bright blood. This may be repeated a few times, the whole amount of blood lost not being very great, and this is followed by a slight, but persistent, bloody discharge, which lasts for weeks. At this time it is rarely bright, fresh blood, but of a dirty, brownish color. Usually there is no pain, and the patient feels perfectly well.

In one case which came under my observation,

there was the history of there having been a fall from a carriage some three weeks previously, and I found, on examination, retroflexion of the pregnant uterus. The uterus was replaced bimanually, and held in position by a pessary, but, as the flowing persisted, she was kept in bed for some weeks, hot-water injections given three times a day, and at the end of six weeks it stopped, and pregnancy went on uninterruptedly to full term.

Many of these cases, if left untreated, and the patient allowed to go about and exercise as usual, would result in miscarriage. The hæmorrhage seems to be the result of congestion, and though the cause may not always be so apparent as it was in the case referred to, yet the rest should be as rigidly enjoined.

Hæmorrhage following miscarriage due to the presence of a portion of the placenta should be energetically attacked, by thoroughly emptying the uterus. If the miscarriage occurred between the second and fifth month, at which period of pregnancy the placenta is most likely to remain, I should not wait more than a few hours before taking measures to remove it. The dangers of delay are renewed hæmorrhage and septicæmia from decomposition, while the advantages of prompt action are that the cervix is usually so relaxed that the retained after-birth can be easily removed, and the patient is not in the weakened and exhausted condition which a continuance of the hæmorrhage or the onset of fever would occasion. In my experience, if the placenta does not all come away with, or soon after the fœtus, it will not come spontaneously, and I have usually found it adherent over a small area at the fundus, the free portion coming down in the cervix and protruding. This is deceptive, for it gives the impression that it is detached, but held in the narrow cervix, and hopes of its being spontaneously expelled are aroused, which are quite sure to be disappointed. The finger, placental forceps, or various scoops which have been devised should be vigorously used under ether, until all of the placenta possible has been removed, leaving a roughened, shreddy surface where it was adherent.

A few words as to the value of, and indications for, internal remedies: The ones most commonly used are ergot, gallic acid, hamamelis, hydrastis canadensis, and iron.

With ergot I have been disappointed, except in a few cases of fibroid during the time when the tumor seemed to be growing toward the interior; that is, changing from the interstitial to the submucous variety. When it had once got within the cavity and had become pedunculated, the ergot seemed to lose its effect. It has also proven of use in cases of subinvolution; but where the trouble is seated in the mucous membrane, as in cases of hyperplastic endometritis, for example, I have usually seen very little benefit, as regards the hæmorrhage, from its use.

Hamamelis alone, or with equal parts of ergot, I have also frequently given, but have been disappointed with the result. The mixture is exceedingly disagreeable to take, and has very little effect on the hæmorrhage.

With gallic acid I have been better pleased. Five to ten grains given in a wafer every three or four hours has often checked the flow, especially in cases where there is a great deal of passive congestion from some misplacement or inflammatory condition about the uterus.

A good deal has been written lately in favor of hydrastis, and especially in Germany, surprisingly good results have been claimed in cases of menorrhagia due to endometritis and other pathological conditions of the lining membrane of the uterus. I have tried it only in one case, and then with no apparent benefit. It deserves a more thorough trial.

I have alluded to iron in speaking of atony of the uterus, and have often found it of great value in young women whose only complaint is excessive menstruation, and in that rare class of cases, chlorosis with menorrhagia. The tonic effect of the iron seems to be all they need.

The subject of uterine hæmorrhage is so wide a one, that I have been rather embarrassed by the variety of aspects under which it might be considered. Many points of great interest have necessarily not been alluded to, and the consideration of those which have been touched upon has had to be brief. Still, some light may have been thrown on some of the more obscure causes of uterine hæmorrhage, and I trust that the discussion will add much more of interest to this familiar subject.

NOTES OF PROGRESS IN PHYSIOLOGY.

BY JOSEPH W. WARREN, M.D.,
Instructor in Physiology in the Harvard Medical School.

Unexpected but not altogether inexcusable hindrances have of late prevented that regularity and fulness in these reports which ought to have been observed by the different writers. There are, in consequence, some important extensions of knowledge calling for mention, which are no longer absolutely new to some, although they are not as yet generally familiar to those who do not have special opportunities to keep thoroughly posted in physiological matters. This consideration will, I trust, excuse such an aroma of antiquity as may be detected by delicate nostrils in this report.

THE MECHANISM OF DEGLUTITION.

Some interesting additions have been made in the past few years to our knowledge of deglutition. Formerly this act was described as a comparatively simple peristaltic movement by which the substance swallowed was carried along gradually through the œsophagus. It was said, for example, that "the normal process of swallowing is accomplished by a series of contractions, beginning at the fauces and ending at the stomach. Each portion of the mucous membrane receives in turn a stimulus from the contact of the food, followed by excitement of the corresponding muscle; so that the alimentary mass is carried rapidly downward by reflex action. Section of the pneumogastric nerves destroys sensibility and motive power in the œsophagus, and consequently interferes with deglutition."[1]

The movement seemed to begin by the action of the tongue in shoving the substance to be swallowed into the pharynx, assisted perhaps by some suction, whereupon the muscles of the pharynx and those of the œsophagus, by a succession of movements, would complete the transferrence of the bolus from the mouth to the stomach. It was also considered by some, that the force of gravity was a material aid. A number of researches carried on by Kronecker and his pupils (notably Meltzer), have radically changed this idea of the

[1] Dalton's Physiology, Seventh Edition, 1882, p. 487.

process and have shown it to be a most interesting and complicated proceeding.[2]

Several considerations serve to make it clear that a peristaltic movement of the ordinary slow and progressive character could not be the important factor in the act. When a swallow of a very cold liquid is taken, the impression of the cold arises in the stomach too soon to be explained by the peristaltic action of the œsophagus. It had also been observed in cases where caustic substances had been swallowed, that the corrosion occurred in spots or patches and not over the entire surface of the œsophagus, as would be expected were simple peristaltsis in play. As to any important part being played by gravity, it should be remembered that many animals swallow well and constantly against this force; and in the experiments with the human œsophagus, the experimenters found that they swallowed with equal speed uphill, that is, with the head down.

It became evident, then, that the important force in swallowing must be produced by the quick action of striped muscles. Falk had shown that with the act of swallowing, a marked rise of pressure occurs in the pharynx. He demonstrated this by slipping a flattened tube along the surface of the tongue, so that it lay below the soft palate. The external end of this tube was connected with a water manometer, which shows a pressure of at least twenty centimetres for each swallow. The new view of deglutition thus founded, was much extended and experimentally established by the ingenious and irksome experiments of Meltzer, made chiefly upon himself. Meltzer found that on auscultation of the stomach, or more exactly just to the left of the xiphoid process, when a liquid or soft mushy food is swallowed, two very different sounds may be heard. In some few cases a clear hissing sound, as though the liquid were squirted directly down into the stomach. This squirt sound (Durchspritzgeräusch) is heard immediately after the act of swallowing begins. Far more frequently, but by no means always, a quite different sound is heard as though air or a liquid were pressed slowly through a contracted sphincter. This squeeze sound (Durchpressgeräusch) occurs six to seven seconds later than the squirt sound. The two are not heard together, although occasionally a dull sound or a very slight squirting is followed later by a fairly clear squeeze sound. The squirt sound is heard most readily in cases with a disposition to vomiting or eructations, and is clearly not the normal condition. These sounds are an interesting confirmation of the earlier experiments of Meltzer, which must now occupy our attention.

At first, experiments were made by placing a recording apparatus in the œsophagus of a dog, and determining the speed with which the contraction passed along this organ. This method proved to be impracticable and Meltzer then made use of his own œsophagus. He found that he could introduce rubber tubes into his pharynx and œsophagus and, after some practice, retain them quite well. The use of cocaine would probably render a repetition of these experiments much pleasanter than Meltzer found them to be. The tubes carried little balloons of thin rubber which could be blown up when the end of the tube reached the part whose movements were to be noted. The open external ends of the tubes were connected with Marey drums, and thus a graphic representation of the time and character of the various movements of the œsophagus in swallowing was recorded upon a revolving cylinder. Having then one balloon lying in the pharynx, and so little distended as not to interfere with the respiration, the commencement of the swallow could be exactly noted. The balloon of the second sound was placed in the œsophagus at various depths. Whatever the position of the second or œsophagus balloon, it was found that swallowing of a liquid compressed it at almost the same instant as it did the balloon lying in the pharynx. Even the deepest attainable part of the œsophagus showed this movement after an interval not greater than one-tenth of a second. The movement has a sharp and quick beginning, like the rapid contraction of a striped muscle. In other words, a liquid is swallowed directly or squirted at once from the pharynx to the lower end of the œsophagus. This was also demonstrated by swallowing acids; it was found that a piece of litmus paper lying in the opening of the sound just above the diaphragm, and which could be easily drawn up inside the sound, was colored by the acid almost instantly, that is, long before a peristaltic movement could have carried the liquid to this point. Then, too, the compression of the balloons was greater for larger amounts of liquid, so that it was actually caused by the passage of the swallow. The movement of the pharynx balloon is really a double one, for the sharply ascending first portion is caught in the early part of its quick descent and transformed into a flatter curve, which falls off much more slowly. The explanation of this, as we shall see presently, is that, while the first movement of swallowing is short, sharp, and quick, as from the action of striated muscles sending the swallow through the entire œsophagus, there follows upon this in the pharynx the contraction of the constrictors, and the movement of this group of muscles begins to manifest the slow character of peristalsis, although the muscles are striped.

In the œsophagus, on the other hand, the rapid first movement is followed by a perfectly distinct second movement taking place after an interval which increases as the sound is shoved farther down. This second compression has a much more distinctly peristaltic character; the curve rises very gradually, has a long flat top and falls off slowly, behaving exactly as though caused by smooth muscles. The duration of this second peristaltic movement increases as the measurement is made in a lower part of the œsophagus. While there seems to be a gradual increase for each centimetre passed over, very marked differences are observed in several regions. It was found that the upper portion of Meltzer's œsophagus, about six cen-

timetres of it, compressed the balloon for two to two and five-tenths seconds; in a second division, about ten centimetres long, showed a wave of compression whose length was six to seven seconds; and in the third division, of rather uncertain length, the compression lasted nine to ten seconds. This is in general accord with those researches (Gillette), which have shown that the œsophagus may be considered to have three portions in which the muscles are striped, mixed, or altogether smooth. Not only do these three divisions show this peculiarity of the duration of contraction, but a similar difference is observable in the interval between this and the preliminary curve caused by the passing swallow. In the upper six centimetres of the œsophagus, the second curve begins for all points at nearly the same time, or about one and two-tenths seconds after the beginning of the first curve. At eight centimetres from the top of the œsophagus this interval is about three seconds and remains nearly the same for the entire second section. Measured at a point eighteen centimetres from the beginning, the interval becomes six seconds or slightly more, and increases very little for the remainder of the œsophagus; the third division. A moment's reflection will convince the reader that although the act of deglutition contains movements which have a peristaltic character, the act as a whole is really much different from ordinary peristalsis. The swallow is thrown down the gullet by a vigorous muscular contraction, after which the pharynx and the sections of the œsophagus contract in succession. Each division contracts after its peculiar interval, and remains contracted until the division below has taken up the movement, thus ensuring that all substances which have not passed on shall be pushed downward, the path upward being completely shut off. The peculiarity of contraction in each segment is due to its structure, the succession depends upon the nervous system.

Meltzer was unable to put a balloon lower than a point about two centimetres above his diaphragm and obtain legible curves. The action of the cardia could not, therefore, be studied by this method. In the rabbit, it is easy to expose the cardia and watch it. Its normal condition appears to be one of complete rest. Irritation of the superior laryngeals sets up the action, and in about two seconds the cardia is seen to contract and to roll inwards into the stomach. The cardia behaves, then, as a section of the deglutitive tract, only the movements here occur much more rapidly than in man. This behavior of the cardia remains the same as to character and time, even though the cardia be cut away from the rest of the œsophagus. The movement, then, is not due to simple muscular continuity, and the cardia has the same independence which Mosso had shown for various segments of the œsophagus. When, however, the vagi are cut, the stimulation which causes the movements above is not followed by any action of the cardia.

The auscultation of the process of deglutition, then, admits of the following interpretation: When the swallow of liquid or of a semi-liquid mass is thrown down the gullet, it stops in the neighborhood of the cardia, which is normally closed. If, however, its muscular tonus is faulty, the liquid may be thrown at once into the stomach, and the squirt-sound is heard almost immediately after the movement of the larynx, which indicates the beginning of the swallow. Meltzer found an interesting confirmation of this view in the circumstance that those persons who had a good squirt-sound lost it when appropriate treatment had improved the closure of the cardia, and lessened their tendency to vomit easily. Normally, however, the swallowed material is retained before the cardia, until, in due time, the contraction of the lowest division of the œsophagus pushes the mass through the orifice; this takes place from six to seven seconds after the swallowing begins, and, therefore, the squeeze-sound is heard after this interval, and not immediately, as the squirt-sound is. Any one who has ever watched a "beer duel," or participated in one, will appreciate this difference in the behavior of the cardia.

The question is now naturally suggested as to what combination of muscles produces the throw of the swallow through the entire œsophagus. Various considerations and experiments make it evident that mylohyoids are the chief factor in this movement. It cannot well be attributed to the constrictors of the pharynx. The position and relations of the superior constrictor seem to preclude its action, and the middle and lower constrictors are apparently too feeble to cause so vigorous a movement. Moreover, Meltzer cut these muscles, in dogs, and found the act of swallowing unaffected, although the effectual closure of the glottis appears to have been hindered. The constrictors, then, are reserve muscles which come in to aid and complete the first movement, but do not cause it. It is, also, not easy to see what muscles of the tongue itself should do much more than to press the tip of the tongue against the hard palate. The movement which must be made is the lifting up of the middle of the tongue, and this neither the muscles of the tongue proper, nor any of the associated muscles, except the mylohyoids, seem to be able to do.

The palato-glossus is absent in many animals which swallow well, and the styloglossus may be cut in the dog with no alteration of the movement. The view that the mylohyoids play an important part in the process is as old as Magendie, and had been accepted by some other physiologists, although the true nature of the movement was not apprehended. Meltzer had cut the *nn. mylohyoidei* in a dog, and found his ability to swallow solids and liquids very much lessened. He learned rapidly to snap at food in such a way as to carry it at once into the pharynx, but had especial difficulty in drinking. Some muscles which are supplied by the *n. hypoglossus* are also essential for the act, and these seem to be the longitudinal muscle of the tongue (pressing the tongue against the palate) and the hyoglossus. The activity of the latter, as well as of the mylohyoids, is easily accessible to demonstration with the fingers. Meltzer then details the first part of the act of deglutition in these words: "By pressing the tip of the tongue on the palate, the exit forwards is shut off; then the mylohyoids contract, so that the mass to be swallowed is put under high pressure and forced in the direction of least resistance, that is, backwards. Almost at the same time the *mm. hyoglossi* also begin contracting and, especially those portions which are attached to the cornua of the hyoid, cause the free surface of the tongue, which at rest looks upwards and backwards, to move backwards and downwards upon the epiglottis, and close it mechanically. The rapid narrowing of the space between the mylohyoids and the palate which is thus brought about also raises the pressure there rapidly.

This effect is increased by the pull of the *mm. hyoglossi*, which gives the tongue a backward and downward movement. Thus liquids and soft foods are squirted down the entire pathway to the stomach before contractions of the pharyngeal or œsophageal muscles can manifest themselves. Fragments which happen to remain in the pharynx are sent down later by the succeeding contraction of the constrictors and with a slowness peculiar to these muscles."

The nervous relations of the different portions of the path are very interesting. We must suppose that the innervation is controlled by six groups of ganglion cells, arranged in a row. The first group gets its stimulus from the periphery, and communicates its signals to the others in turn, these having no sensory communication with the outside world, except through the first group, but each group has motor fibres for the muscles which it controls. In each group of ganglion cells, the movement, although probably progressive, is very rapid, while the passage of the signal from group to group is slow, and grows slower as we get further from the first. Only the third group occupies a peculiar position, and has some sensory relations of its own. This is evident from the fact that when an eructation occurs, although no swallowing movement of the mylohyoids or constrictors takes place, a regular movement of the œsophagus begins, and continues just exactly as though the impulse came from the mouth, as in an ordinary swallow. Nothing resembling an antiperistaltic movement was observed. This peculiar relation of the third group of ganglion cells seems also evident from Quincke's recent experiments. He introduced water or air into the œsophagus of a dog through a sound whose opening lay from five to fifteen centimetres above the cardia. In this way a succession of contractions in the œsophagus was originated, but no proper swallowing occurred; that is, the upper segments of the tract (mylohyoids, pharynx) remained at rest.

Very curious, too, is another relation existing between these ganglion groups, for the second swallow taken shortly after the first inhibits the secondary contraction of the first swallow, and none occurs until the proper interval after the second swallow has elapsed. Indeed, a number of swallows may occur, one after the other, and the secondary, "peristaltic" movement will not occur until after the last swallow. According as the balloon lies in the first, second, or third section of the œsophagus, the interval between swallows may be nearly one-and-one-fifth seconds, three seconds, or from five to six seconds, respectively, without the secondary movement for the section proving itself. At the same time, a record is made showing that with each swallow the liquid is sent down. Kronecker and Meltzer seem to think that the liquid is held back until the final squeeze comes, although they apparently admit that the tone of the cardia appears to be weakened, and that after a succession of swallows, the squirt-sound is more readily heard. Ewald believes that the liquid works through the cardia (gravity?), and that air, perhaps, remains behind and is squeezed through when the secondary movement comes, the latter acting as a sweeper of the œsophagus. On the other hand, Meltzer especially notes that the contraction of the cardia (rabbit) may be inhibited by a succession of swallows, and that when these are over and the contraction does come, it is more intense, and lasts longer, than after an ordinary swallow, and Quincke saw on an opened stomach (dog) that the liquid was squeezed through noiselessly in from four to five seconds.

Both Ewald and Quincke maintain that the admixture of air is necessary to the production of, at least, the squeeze-sound, and that the time relations of this do not prove that the liquid swallowed remains in the œsophagus until it is squeezed through by the later movement. They also consider that the quantity and quality of the contents of the stomach materially affect the second sound. Evidently, much more must be done before this point is settled, and before much diagnostic value can be attached to it.

Very important too, are Meltzer's observations on the relations of the centre for deglutition to other nerve centres. His article is so full of meat as to be ill adapted for abbreviation and only the principal results can be noted here. The act of swallowing is a reflex act, it goes on independently of the will. We may will to contract the mylohyoids and lift the tongue against the palate and thus start the swallow reflex. Irritation of the central end of the superior laryngeal sets up the movements with great precision, indeed, "the mechanism of swallowing is one of the most exact and best controlled reflexes in the entire animal organism." The centre lies in the medulla oblongata, and the movements are complete in narcosis or when the brain is cut off, or when the medulla oblongata is separated from the medulla spinalis. This swallowing centre, in the floor of the fourth ventricle, has important relations to other centres, and the study of these opens up an instructive view of the association of inhibitions and suggests valuable therapeutical applications.

As we have seen, each reflex stimulation to swallowing sets up first an inhibitory action and then a discharging action in the centre for these movements. But there is also an effect on the inhibitory centre of the heart, for the heart-beats increase in frequency when we swallow and the increase grows greater with the increasing number and frequency of the swallows. This period of quickening is followed by one during which the heart-beats are slowed, but the slowing is not as marked as the quickening. There also appears to be an affection of a vasomotor centre, for the blood pressure as indicated by the fulness of the arteries sinks. Unfortunately, the conditions are not favorable for an exact direct measurement of the blood pressure on animals. When the swallowing centre is active the respiratory activity is lessened. This is not merely due to a mechanical interference on account of closure of the glottis for it is manifest in animals breathing through tracheal cannulas. It is found that the breath can be held more easily when small quantities of an indifferent liquid are repeatedly swallowed.

Very remarkable, too, is the fact that similarly we can, by repeated swallows, inhibit the contractions of the uterus, at least in the earlier stages of parturition, and the erection of the penis. Commonly, to be sure, the centres for these intimately related activities are supposed to be in the lumbar region of the spinal cord, but another centre for parturition has been found in the medulla oblongata, and there are other grounds for supposing that there may also be a higher centre for the erection. Less precisely established is the influence of the inhibitory process in swallowing upon various muscular contractions. The possibility of

stopping hiccough (spasm of the diaphragm) by small and frequent swallows, is not merely a popular notion — and spasmodic action in the glottis (from "swallowing the wrong way") can be quieted (inhibited) by continuing to swallow.

We have then the important general truth that summation and radiation are not merely observable of reflex movements, but the same general laws are applicable to reflex inhibitions as well. Therapeutically, too, these results are very suggestive, but the very simplicity of the means to be employed will probably continue to prevent their use. Perhaps we have in frequent small swallows of water a better and more efficient means of stimulating a feebly-acting heart and relieving a fainting fit than the ordinary treatment affords. Numerous other applications will readily suggest themselves.

Before leaving this subject, it may be mentioned that Prof. Harrison Allen[3] has suggested an ingenious device for registering the movements of the soft palate. I will add, however, as a matter of historical interest that this is essentially the plan proposed by Czermak,[4] about thirty years ago, which in turn was an adaptation of a method made known by Debrou at a much earlier time.

Debrou (1841) had introduced a probe through the nose and observed the movements of the external tip incident to the movement of the other end resting upon the soft palate. The mention of this in the German translation of "Donder's Physiology," (1856) led Czermak to devise a modification of the method. Using an iron wire 200 mm. in length, he turned over one end so as to make an eye (Oehse) 12 mm. broad, which he filled and covered with wax. At the other end the wire was bent at a right angle to the same side and in the same plane as the eye. This was so introduced that the narrow edge of the eye came to lie upon the soft palate, whose rise and fall would then be indicated by the rotation produced in the pointer before the nostril. Czermak says that he could not at the time have any of the devices made which occurred to him as likely to render the reading of the rotations easier; he does not seem to have returned to the investigation later.

Professor Allen uses a plain straight wire with a bulbed end to rest upon the soft palate. Just in front of the nose is a vulcanite support for a wire running up to a holder, which is merely a portion of a head mirror. Thus a fulcrum is obtained to produce movement of the external end of the rod, which has a fine flexible termination for writing upon the smoked paper of a revolving cylinder. Such lateral movements as occur may be registered by working with a horizontal drum.

— "Theism" is no longer to be understood merely in its old-fashioned philosophical sense. The word has been rehabilitated and is applied by an eminent medical contemporary to the complexus of symptoms caused by excessive tea-drinking. *Thea* as well as *Theos* claims a philological parentage in Theism.

Clinical Memorandum.

REPORT OF A CASE OF EXTRA-UTERINE PREGNANCY, THE FŒTUS BEING RETAINED FOR THIRTY YEARS AND BECOMING A LITHOPÆDION.[1]

BY W. H. FALES, M.D.

In giving the history of this case, I hoped to quote from the records of the physician who attended Mrs. A., during her illness and who, as I understand, took extensive notes, but I am unable to do so, owing to his death a few years since, and the subsequent destruction of his records.

I am fortunate, though, in that such information as I have, comes from a twin sister who is still a remarkably vigorous woman both mentally and physically, and whose statements, as far as they go, are undoubtedly correct.

Mrs. A. was married September 24, 1844. Never had any miscarriages. She was delivered of a perfectly healthy child January 29, 1848.

Early in January, 1856, she became, as events proved, pregnant again, though her condition at the time was merely surmised, as menstruation continued to be present and in fact existed, with more or less regularity, throughout her entire pregnancy.

It was not until the middle of May that the attending physician made a positive diagnosis of pregnancy, basing his opinion on fœtal movements which became manifest at that time.

Early in March of the same year while visiting friends, she fainted, vomited and complained of considerable epigastric pain. There was no flowing at this time. The following day she rode home, a distance of four miles.

Directly after this, she had three so-called inflammatory fevers characterized by abdominal pain, excessive tympanites and uncontrollable nausea and vomiting. During one of these attacks an abscess formed just above the pubes, which opened but did not discharge much.

Counting from the middle of May, when fœtal movements began, October 1st would be the probable date of her confinement. About that time the physician was summoned, not on account of labor pains, as she *never* had these, but for excessive and painful movements of the child. These were always very marked, and caused her the utmost inconvenience. As she expressed it, she felt more life with this child in two hours than during her entire previous pregnancy. October 13th, the physician was again called, for the same reason. At this time "something was rubbed on the abdomen," after which the movements grew less and less, and finally ceased. For the next ten years she was an invalid, though nothing very explicit could be obtained as to her condition. She was generally miserable and had a number of attacks of abdominal pain, sometimes accompanied by icterus.

During this period the tumor very gradually decreased in size, finally remaining stationary and causing no trouble except a feeling of weight when standing or walking too long.

Her subsequent health was good until about two years ago, when a malignant growth attacked her larynx, which eventuated in her death December 24, 1886.

[1] Read before the Section of Obstetrics and Gynæcology of the Suffolk District Medical Society, April 20, 1887.

The autopsy was performed September 26th, Drs. Bill and Metcalf assisting.

The body was very much emaciated. The tumor was apparently situated about in the median line, but on palpation was found to extend downwards and to the left, the contained fœtus occupying a sacrum-left-anterior position, but entirely out of the pelvic cavity, the base of the skull being on a level with the umbilicus. On making the incision the tumor was found to be adherent to the abdominal wall, and it seemed as though it would soon have made its way through, either from pressure or ulceration, so thinned had the structures become at the point of its adherence.

It was almost lying loose in the abdominal cavity, the only points of attachment being the one just referred to, the pedicle, and some small adhesions to the intestines.

The intestines were ranged round the tumor — none in front of it — and were one mass of adhesions, forming with the abdominal walls the sac, as it were, containing the tumor.

The pedicle passed directly downwards, enclosing the uterus and then fading out gradually into the peritonæum. Nothing that would answer for a placenta, or the remains of one, could be found.

With the tumor I extracted the fundus, fallopian tubes and ovaries, which furnished no points of interest. Any further examination was denied. The autopsy suggested an extra-uterine pregnancy of the abdominal variety, but the history points rather to a ruptured tubal becoming an abdominal.

To epitomize the various dates:

Mrs. A. was married in 1844; first child four years later; second pregnancy eight years later; probable rupture of tube and subsequent attack of peritonitis at third month; death of fœtus at ninth month; death of Mrs. A. from cancer of the larynx thirty years later, the fœtus having become converted into a lithopædion.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

APRIL 20, 1887. DR. JAMES R. CHADWICK in the chair.

DR. F. H. DAVENPORT read a paper entitled

UTERINE HÆMORRHAGE.[1]

DR. FARLOW said, I was very glad to hear Dr. Davenport's remarks about the necessity of more carefully investigating cases of hæmorrhage which occur at the time of the menopause. The physician is too often satisfied with having made a diagnosis of "change of life" and allows the disease of the patient to go without proper examination. In regard to retro-version or flexion with adhesions, it is not the old chronic cases which give rise to hæmorrhage, but the acute or subacute inflammations which occur from time to time in the chronic cases.

With reference to remedies, I have often found ergot unsatisfactory, though sometimes of considerable value. I have never used gallic acid. Aromatic sulphuric acid has proved of service in many cases in which ergot had failed. I have been much interested in the paper of Dr. Wilcox on the Use of Hydrastis Canadensis. I have used it in only half a dozen or so cases, and have not yet sufficient data from which to form an opinion.

DR. SWIFT said that hæmorrhage was not confined to chronic cases of retro-displacement with adhesions. Besides the acute cases caused by falls, etc., he had seen cases of a subacute character where the hæmorrhage began with an increased flow at the menstrual periods, going on to metrorrhagia. The uterus in these cases is freely movable, and by replacing it and adjusting a pessary the hæmorrhage is stopped.

He had been using hydrastis lately in cases of profuse menstrual flow, with good results. It does not work well in all cases, and he could not say, at present, in what class of cases it would prove most efficient.

DR. INGALLS said, to obviate disappointment from the effects of ergot, I have always considered it best to give it in infusion, prepared at the time it is required.

Edes says, "the active principle of ergot is volatile and is easily decomposed," if we use the fluid extract, which is the best preparation next to the fresh infusion. The reputation of the maker should be of the highest.

DR. L. V. INGRAHAM mentioned the following case. In July, 1885, I saw a young married woman, then three months pregnant, who had a sudden and profuse hæmorrhage. She had been standing for about an hour and was tired and faint, other than this she had made no unusual exertion; there was no history of a fright or any injury, and she had always been well up to this time, with the exception of dysmenorrhœa for a year previous to her pregnancy. The flow was quite profuse for three days, then lessened markedly except during, and for about an hour after micturition or defecation, when the flow was very copious. She had nearly ceased flowing at the end of the third week from the time she was taken, but was advised to stay in bed until after the next menstrual epoch. At this time, although she was not imprudent to my knowledge, the hæmorrhage came on as freely as at the third month and lasted four or five days. At the end of two weeks the flow had nearly ceased again, and she insisted upon getting up at all hazards. At the end of the fifth month there was another free hæmorrhage for four days after, when the discharge became thin and brownish. At each succeeding menstrual epoch there was a copious hæmorrhage lasting from three to five days, and during the intervals the thin brownish discharge continued. At the ninth menstrual epoch, labor began on Friday night a little before midnight, and after an easy labor her child, a boy weighing three pounds, was born. Through the fault of a messenger I did not see the lady until Sunday night. The physician in charge told me that he employed Crede's method in the third stage of labor, but without success; he then used placenta forceps but failed, and the patient being very much exhausted he made no further effort until Sunday afternoon, when after etherizing the patient, with the aid of two able assistants he removed the placenta. It was entirely adherent. The placental site was at the fundus uteri. At no time during the pregnancy were any clots passed; at the times when the flow was profuse the patient complained of "cramp in the abdomen," and she steadily lost in weight and was very much emaciated when her

[1] See page 124 of the Journal.

child was born. She has never been well since. Her child is living and is well.

DR. CALL asked if any members had noticed a tendency to profuse menstruation in patients with organic heart disease. Dr. Bowditch had told her he thought that subjects of the latter were prone to menstruate too freely. He then spoke of a case of exceedingly profuse uterine hæmorrhage in a young girl who had no local pelvic trouble, but who had serious organic disease of the mitral valve, probably congenital.

DR. CHADWICK. It seems to me that I have obtained better results from the continued use of ergot for a number of weeks, substituting for it some of the mineral acids at the time of the hæmorrhage. In the treatment of fibroids, I have, in some instances, obtained much more marked effects in reducing the size of the tumors, from combining with ergot the muriate of ammonia, as first recommended by Atlee.

In the use of Chian turpentine for uterine cancer, I soon recognized its inefficacy to arrest the progress of the disease, but found it a powerful hæmostatic. I consequently extended its use to uterine hæmorrhages from other causes, with occasional surprising effects in otherwise intractable cases. I recall one young girl who brought me a letter from Dr. Barker of New York. She had been flowing most of the time for two years, despite the persistent treatment in the Free Hospital for Women, and elsewhere, by astringent applications, by curetting, dilatations of the cervix, and all the customary internal medications, without avail. The Chian turpentine arrested the hæmorrhages immediately, and they never recurred. In a young lady of twenty-six years, now under my care, whose ovaries were removed by me last spring for rapidly growing and hæmorrhagic fibroids of the uterus, after three months' interruption profuse hæmorrhages recurred, but have been repeatedly arrested by the injection into the uterine cavity of strong acetic acid. As this acid does not coagulate the blood, its use does not expose the patient to the danger of septic infection. I have been able by this means to keep my patient in perfect physical condition.

DR. W. H. FALES reported

A CASE OF EXTRA-UTERINE PREGNANCY, THE FŒTUS BEING RETAINED FOR THIRTY YEARS, AND BECOMING A LITHOPÆDION.[1]

DR. FITZ said the specimen shown by Dr. Fales represents a longer interval of time than any he remembered to have seen. Older examples are known to occur, but their number is few. The cavities of the head and trunk are well defined and easily differentiated. He thought it not unlikely that the earthy salts deposited in these fœtuses might subsequently be absorbed to a greater or less extent, and parts of the fœtus be discharged externally. A specimen in the Warren Museum favored this view, as it showed a completely calcified head and trunk, but with extremities which were partly calcified and partly macerated. As the age of the latter specimen was seven years, it indicated the degree of calcification which might take place in this time.

Dr. Fitz said, in reply to Dr. Chadwick's question, that the diagnosis of lithopædion evidently depends upon the presence of an abdominal tumor following the history of pregnancy, but without the delivery of the fœtus. With such a history, the longer the tumor persisted without undergoing enlargement, the greater was the probability of its being of the above nature.

DR. Z. B. ADAMS said that a peculiar interest attached to this case, in his mind, because the physician who attended the woman in 1834 was Dr. Enos Hoyt, of Framingham, and his grandson, Dr. Enos Hoyt Bigelow, of that town, had lately reported in the *Boston Medical and Surgical Journal* a case of abdominal pregnancy, occurring at or near the time of the death of the subject of this lithopædion.

With regard to Dr. Bigelow's case, he would like to ask the opinion of members as to the best method of dealing with the placenta in any operation to remove the child. Of course, the placenta can be let alone, and this would be obligatory in a case where this organ was, as shown at the autopsy, firmly fixed upon a large surface of the parietal peritoneum. It had occurred to him that some attempt might be made by ligature and cutting away, but the hæmorrhage would probably be uncontrollable. If left behind, no drainage would be likely to avert death from septicæmia.

Considering this difficulty, Dr. Adams, while advising abdominal section, did not strongly urge it. The fact that the case reported to-night was known and discussed by Dr. Bigelow's patient and her family, influenced them to oppose operation. It may appear strange that these cases should be so difficult of diagnosis. It should, however, be borne in mind that symptoms of pregnancy are chiefly subjective, and are, in a hysterical woman (as was the case here), of doubtful value. A uterus bound down by adhesions, the abdomen greatly distended by fluids and gases, with tenderness, the absence of fœtal heart-sounds or motion, and a previous history of abdominal pain and peri-uterine inflammation, gave in the present case occasion for doubt.

DR. CHADWICK. This lithopædion is a beautiful specimen of a very rare condition. It is curious to speculate upon the conditions causing the calcarious deposits in one case, and not in another. We seem to have data to guide us in determining the commencement of the stowage of an extra-uterine fœtus. You may remember the mounted skeleton of the mature fœtus that I presented to the Section last winter. It had died at full term, and been carried by the woman without serious inconvenience for nine years. It was encysted and packed solidly in the remains of its own soft tissues, which had undergone a fatty degeneration, so as to be what is called adipocere. The diagnosis of extra-uterine fœtation is of extreme importance, but often fraught with great difficulty. In another case that I had last year, I was able to make a correct diagnosis at the ninth week from the history and physical signs. This was confirmed three days later by the examination by Dr. Fitz of the decidua, and by finding, by means of the uterine sound, that the uterine cavity was empty, and measured four inches in length. The treatment was directed to killing the fœtus by the electric current, which was successful, as proved by the extraction of the bones through the vagina by Dr. P. J. Murphy, of Washington, five weeks after she left my care. This is the first case on record in which the efficiency of this method of treatment has been absolutely demonstrated by the subsequent extraction of the fœtus.

DR. A. F. HOLT showed to the Society two interesting morbid specimens, one showing a remarkable

[1] See page 131 of this number of the Journal.

degree of post-mortem softness where the stomach and diaphragm had been perforated, and the pleura covering the lower part of the left lung destroyed. These organs were from the body of a girl fourteen years of age, who died of meningitis. The autopsy was twelve hours after death. The other showed an extraordinary inhalation of soft mud by a new-born child. The trachea and larger bronchi were nearly filled with this substance, and it had even penetrated the smaller air-passages in some parts of the lung. This child was born in an out-house, and was immediately carried by the mother to near the edge of a neighboring mud-hole, where she buried it.

AMERICAN NEUROLOGICAL ASSOCIATION.[1]

THIRTEENTH ANNUAL MEETING AT LONG BRANCH.

JULY 20TH.— AFTERNOON SESSION.

DR. DANA, of New York, read a paper on

HEREDITARY TREMOR.

The writer remarked that he thought this subject had not been given the attention it deserved; stating that the child can even be born with it, and mentioning one case where it occurred in all the members of a family, in another case where it appeared in a watchmaker, yet he could adjust the finest works of a watch, as the tremor can be controlled by the will temporarily; ordinarily the health is good, and the tremor ceases when the patient sleeps. The grandfather had been very intemperate; there were nine of his own family, one was insane, and another fond of drink; all of them lived to advanced life, seven of them had thirty-four children, and all of these had the tremor, in some epilepsy developed, so that in this instance the tremor developed in three generations, the total number in which it appeared being forty-four. In another family there were three cases, and in another there were two. In the family of three children, the father was of good habits, a son thirty-five years of age had had the tremor since infancy; he is rather addicted to the use of alcohol and tobacco; his brother, who is also afflicted, is a man of very steady habits.

In this disease the head and neck are not affected as in senile tremor; it also seems to occur more in men than women, it appears to be distinct from paralysis agitans.

DRS. PUTNAM and DERCUM mentioned cases coming under their notice, the same symptoms as described by Dr. Dana being visible.

DR. HAMMOND asked Dr. Dana if he considered this the only form of hereditary tremor. He remembered a case in which the patient could not sit in a chair. The tremor was similar to chorea in its manifestations; he could only trace it back to the mother in this instance; a brother and sister of this patient had it, and also a niece; it did not appear in this man until he was thirty-five years old, and toward the end of his days mental failure commenced, delusions, hallucinations, etc.

DR. DANA replied he was not aware it was hereditary; the tremor he had described in his paper was by no means rare, and he was surprised at it not being found in literature.

A paper was read by DR. GEORGE W. JACOBY, of New York,

[1] Continued from page 113.

ON MICROSCOPICAL STUDIES IN A CASE OF PSEUDO-HYPERTROPHIC PARALYSIS.

The author considered that although much had been done in regard to the primary affections of the muscles as regards diagnosis, it still remains rather obscure and vague from our clinical field of vision, and in order to understand it we must bring its pathology more prominently forward. The histological changes he regarded as not settled definitely.

The first case reported by the reader was a typical one of this disease. The patient was fifteen years of age, seven children in the family, two died, one being paralyzed, the latter probably from diphtheria; no family taint. Patient walked at thirteen months; had convulsions, repeated every four days, after which was unable to walk for four weeks, but afterwards walked as well as ever. At the age of nine years he had a severe fall, confining him to his house for eight weeks. The first symptoms were noticed at the age of twelve years.

On examination by Dr. Jacoby, no atrophy of any muscles could be discovered, his condition was typical of the disease. Two pieces of muscle about the size of a bean were secured and prepared for microscopical examination; the muscle fibres were found to be but half the normal number under the glass, and were also smaller than natural; no hypertrophic fibres were found, although some observers claim they are always there. The speaker remarked that these perhaps could be found in some other muscles of the body. The connective tissue was more than twice the amount in the normal subject. Dr. Jacoby here showed photographs of his dissections illustrating the condition represented in the subject; the question, however, arises as to whence comes this augmented connective tissue. Erb, Friedrich, Buss, Schultze and others have endeavored to describe it. The reader remarked that the fact that the muscle fibres were decreased in number as well as in size, was in itself suggestive of the source of the augmented tissue, and all his specimens went far to prove that the connective tissue had grown to a great extent at least, at the expense of the contractile substance, the medullary corpuscles having originated from the muscle substance itself. In many places the transition occurring can be observed. The writer described carefully the line of investigation followed out which resulted in the confirmation, with few exceptions, of the views of such writers as Charcot, Hetller Eulenberg, Friedrich and others.

From these investigations he remarked, that if now he could be allowed to draw conclusions without, at the same time generalizing, he should, in a measure, differ from some observers; being convinced that in many patients the disease is essentially a chronic inflammation, invading *both the perimysium and the muscle tissue*, he considered it impossible to say what the cause of this process might be unless sought for in a congenital malformation of the muscle tissue itself; such malformation being indicated by the small size of the sarcous elements, as we are accustomed to see them in the earliest stage of embryonal development. But, however this might be, the pathological process consists of a gradual reduction of the muscle fibres into medullary or inflammatory corpuscles, which in turn go to build, partly fibrous, partly cartilaginous, and partly fat connective tissue. The process, which is extremely slow, gradually leads to an augmentation

of myxomatous or other varieties of connective tissue at the expense of the muscle tissue. He would here say that he could not agree with Gower and Buss, that proliferation of the connective tissue is the primary, and the disease of the muscular tissue the secondary process. Either the reverse of this is true, or the process is simultaneous, both in the muscle and the perimysium.

The writer did not hesitate to place the whole process as seen in his specimens, in the same category with the process termed *myositis ossificans progressiva*; had he to describe it in a few words he would call it a *myositis progressiva hyperplastica*. Of the various investigators of the subject during the last few years, he thought Georgeus was the only one who also considers the process a myositis; but he looks upon it as an intestinal myositis alone, and says that he is not prepared to give an opinion regarding the changes in the muscle fibres themselves.

The speaker thought the more frequently careful microscopical examinations are made of the muscular tissue, in the various dystrophiæ, the more are we obliged to come to the conclusion either that from a microscopical examination alone, we cannot always make a distinct diagnosis between the various affections, or that they are as largely admitted to-day, all varieties of one and the same process which unperceptibly blend one with another.

What particularly impressed him in this connection, was that his examination differed so decidedly from descriptions of pseudo-hypertrophic muscles, as given by others, yet notwithstanding the case was clinically a perfectly clear one, it agreed almost entirely in the description given by Friedrich, of the muscle from a case of progressive muscular atrophy. (Case X, page 37) which affection, as is well known, he classed as a primary myopathy, and considered the process to consist of a chronic progressive myositis.

Dr. Dercum stated that he had examined some typical cases last fall occurring in the adult. Also a case in which there were some signs of inflammatory changes in the corpuscles and connective tissue element, in these cases there was an interstitial myositis, but whether it was secondary to the myositis proper it was hard to say.

Dr. Sachs, of New York, presented a paper

ON ARRESTED CEREBRAL DEVELOPMENT WITH SPECIAL REFERENCE TO ITS PATHOLOGY.

The writer referred to the special interest this condition of the brain had to the pathologist, as the opportunities for investigation are few and far between; he drew attention to the histological changes occurring in the cortex; the pathological conditions are extremely varied. A case was mentioned of a child which was perfectly formed in its limbs; before birth, however, the mother was thrown from a carriage; there were symptoms also of mental weakness on the side of the parents. The child would lie on its back and never attempt voluntary movement, objects placed in its hands would fall out; as it grew mental vigor did not increase and finally total blindness set in. The child never uttered a sound except a low gurgling noise if left alone. There was no rachitis, no history of syphilis, and the child finally died from pneumonia; post-mortem the skull was found to be thickened, and there was a large clot in the longitudinal sinus; the brain weighed two pounds, the bloodvessels appeared to be normal. Referring to Mr. Mills' paper last year on "Brains of low Type," he, (Dr. Sachs) thought this brain resembled those at that time exhibited, in many points; he drew attention to the exposure of the island of Reil in his present specimen, also to the retraction of the first temporal convolution, there was a general narrowness of the convolutions; in the right hemisphere the island of Reil was but little exposed. From this and careful microscopical examination he considered it a clear case of retarded development, and not to be attributed to inflammatory conditions.

Dr. Mills considered the histological and pathological conditions of the case were a hard matter to discuss as regards causation; he thought there might be a few cases on record, and this added to them might be of value.

Dr. Amidon remarked he had seen two cases very much like this, in which there was no lesion apparent but there were signs that hæmorrhage had occurred at some time before. He thought hæmorrhage might occur without leaving any trace at the autopsy, and he would ask Dr. Sachs whether it occurred to him that it might have been the same in his case.

Dr. Sachs replied that he had, and also of the accident occurring to the mother in her fifth month of pregnancy, but he thought if hæmorrhage had occurred there would be thickening of the cortex. The child, at birth, was brighter than later on in life. He did not think it was owing to traumatism, but the general circulation may have been disturbed; he thought it more plausible that it was a disturbance of nutrition.

JULY 21, 1887. — SECOND DAY. — MORNING SESSION.

Dr. Lloyd read

NOTES ON A CASE OF THE INSANITY OF DOUBT.

The form of mental disease which has been described by some French writers as the insanity of doubt, has presented itself to my notice in a number of cases, to one of which I will briefly call your attention.

These cases are characterized as a special form of delusion which differs radically from those of grandeur or persecution. These latter rather impel to action, the delusions of doubt restrain from it. The systematized delusion has something rather positive, aggressive and self-assertive. The delusions of doubt are not so firmly fixed; they are changeable, negative, vulnerable, and confessed with timidity and mortification. They are somewhat allied to melancholic conditions, but are not characterized by depression of spirits, (psychalgia), so much as by confusion and perplexity of mind, which exasperate the patient and from which he would be only too glad to escape. He is apt to recognize the perfect character of the morbid states and will willingly take measures to counteract and cure it; sometimes when taxed with it will even joke about it, and it might require a stretch of conscience to pronounce him a lunatic under the law. Hence, it is a species of reasoning mania. Some cases hardly amount to delusions in the narrow sense, the patient does not so much believe a false thing as he is impelled to solve innumerable problems which present themselves to his mind, and which may be as useless as they are perplexing, both to himself and others, and equally imperative. They are exaggerated states of that intense impulse, to solve a problem or discover a mystery which is not infrequently seen in a healthy

mind, hence they are analogous to healthy processes, as is the case always in insanity. Hence, again, they are intellectual in character, although this might be disputed by some in favor of an amorphous moral insanity (so-called) because the follies and perplexities of these cases claim a superficial attention, and are not sufficiently investigated and detailed. A surface view of such a case would not reveal its essential psychioc features.

This particular state, doubt, perplexity, probably lies at the root unconfessed, forming the motive of a certain number of eccentricities and aberrations which are ascribed by some to mere perversity of moral character, and by others are attempted to be shielded under the ample but dark cloak of moral imbecility. Other cases approach nearer a systematized delusion; they present a certain morbid association of ideas which produce luxuriantly various crops of indecision. These patients link their fate to trivial happenings; they will be lost if some unimportant and impertinent fact obtrudes itself suddenly upon their diseased imagination. The vacillation of their minds becomes amusing to the ignorant, but tragic to the immediate family, who suffer, while it is both vexatious and exhausting to the patient, and highly instructive to his physician. All these operations of the so-called intellectual sphere shade into one another and into others; in fact, they form an inextricable network of error, just exactly as broad as the human mind. This condition, however, is not to be confounded with confusional insanity, for these patients have their wits about them, they are not incoherent, but quite connected in their ideas and speech; as indeed is necessary for them to accomplish the amount of hair-splitting and wool-gathering of which they are capable. There is, however, some likeness to the imperative conception, for these patients are compelled quite irresistibly to engage in their morbid penance or dialectic gymnastics in order often to deliver themselves from the limbo of their own thoughts; if one spirit of doubt is laid, a dozen arise to take its place.

Mrs. A. B., a resident of a distant city was brought to Philadelphia, and placed in a hospital for the insane. During the preceding year she had shown change of character and habits, developing symptoms of *folie du doute*, and exhibited it in a variety of ways; had been known to get out of bed twenty times during the night because under the impression that she had not performed the act right, and unless it were performed in a precise manner, it would cause disaster to her. So, again, she obliged her husband to remain in her room with her until she had put on and off again a number of times, one of her skirts, from the same impulse. She reads no papers nor visits her friends for fear of receiving impressions which will haunt her. When dressing, she obliges her husband to hold a pin for her which she must seize just the right moment, otherwise the toilet must be made again. She has sometimes insisted upon his rising in the night, going down stairs, and lighting a certain gas-burner and extinguishing it again in just a certain way, because this was necessary to absolve her from some of her morbid doubts and associations; has not been content until her husband has humored her; on returning to bed he would be subjected to a long cross-examination on the subject. At night she has seen printed sentences before her eyes, suggesting disagreeable and depressing subjects; but these are not true hallucinations, as she does not believe in their reality, yet they are a suspicious symptom.

When she reached Philadelphia her husband placed her in a hotel instead of an asylum, and then told her of his intention to put her in restraint; the lady protested against this indignantly, and bade her husband and the medical profession defiance. A few hours later I visited her; she was a young woman thirty years of age, of not good color and complexion, of sound muscular system, but not well-developed; suggesting physical impairment rather than mental. She had refused to have a physician sent for, but when assured that no wrong would be done her she was once more herself. She conducted her share of conversation on general subjects quite rationally, also speaking of her notions, stating that she knew they were morbid. The patient was very candid and courteous to the writer but could not be persuaded to go voluntarily to the hospital. It was the opinion of the writer after a long conversation with this lady, that it would not only be injurious to take her to an asylum against her will, but that it would probably create a public scandal. Dr. C. K. Mills was called in consultation and also concurred in the same opinion.

It is important to add that this lady had an insane first cousin, and her father had been an excessive drinker. The several cases I have seen presenting these and similar cases, have all probably been of the neurotic or constitutional type.

It has not been the intention in this paper to attempt the naming of a new species of mental disease, but simply to describe certain symptom groups which are no doubt not isolated in any one case, but would probably be associated with other manifestations of disease in any case, which was followed through a long period of time.

Dr. Mills thought the paper would help solve the question as to the disposal of these cases, by an interchange of opinion between the members of the Association. As stated by Dr. Lloyd, he had seen the patient mentioned, and concurred in Dr. Lloyd's opinion. In some cases, it would best serve the patient to be sent to an institution, but extreme care and judgment should be used, remarking that few cases gave such trouble to families as these; and were the doctor to condemn them to be submitted to restraint, were the case to be brought to court, but few juries would concur with the doctors, as the patient appeared to be sane on the especial point at issue, and it would be doubtful if the community at large would judge the patient insane, or even necessary to discipline.

Dr. Gray remarked that, in these cases, he had no doubt as to their being insane, and should not hesitate to put them under restraint, but would not do so unless he well knew the antecedents of the case. In his experience, he had found them exceedingly dangerous cases, as some of them will go a long time without manifesting dangerous symptoms, when, some day, they will commit some terrible deed. The speaker quoted a case, in which the woman had been in that apathetic condition for some time, who had, by actual count, washed her hands four hundred times in one day, and yet, for all medico-legal purposes, would have been considered sane. She had become debilitated, owing to neuralgia and some uterine difficulty, but her mind seemed to recover somewhat under careful medical treatment. He, however, decided to send her to Bloomingdale, and so informed her, stating the

result he hoped to attain in her case; but the day before she was to go, she unfortunately quarreled with her mother on some trivial matter, and set fire to her own clothing, having secretly procured and hidden matches about her person, the sulphurous portion even under the finger-nails, paper being secreted under her arm-pits. This illustrates the danger of these cases. I deem them especially dangerous when left with children; we must take the risk in sending them to an asylum. We must settle this question from a scientific point of view, rather than the medico-legal sense.

Dr. Lloyd, in conclusion, stated that he did not wish to be misunderstood on that point, as he appreciated that there were proper cases for restraint, if they can be taken to an asylum without creating an unfavorable impression upon the patient, and increasing their malady; but in the case he quoted, the husband did not wish the wife to be removed, laboring under the impression that she then had, and as she was capable of reasoning upon that point, claiming that it would cast a stigma upon her (which was reasonable) if she were taken to an asylum. He had pursued the course stated, and which, he was happy to say, Dr. Mills concurred in. In these cases, the surroundings required, he thought, careful consideration.

(To be continued.)

AMERICAN OPHTHALMOLOGICAL SOCIETY.

Twenty-Third Annual Meeting.

THURSDAY.—SECOND DAY.—MORNING SESSION.

CASE OF GLIOMA OF THE RETINA,

by H. D. Noyes, M.D., of New York.

The patient, a child, was first seen when fifteen months old. The eye was enucleated, and microscopic examination confirmed the diagnosis of glioma, which was made prior to operation. The patient was again seen fourteen-and-one-half years later, when sixteen years of age. An artificial eye had been worn. There was not the slightest evidence of a return of the disease.

PSEUDO-GLIOMA.

This case is reported on account of the interest connected with the diagnosis. It was difficult to say positively whether or not there was an intra-ocular tumor. The case was examined by Dr. H. Knapp and myself, and we made a diagnosis of inflammatory trouble, but enucleation was advised, on account of the doubt as to the correctness of the diagnosis, and even if the affection were purely inflammatory, enucleation was the wisest plan, in view of future possibilities. The patient was a boy, aged five years, who, in November, 1886, was thrown from his velocipede, the handle of the machine causing a wound of the left cheek, under the orbit. There was no apparent injury to the eye, and during the winter there was no trouble. On May 4, 1887, he was brought to the author. There was, at this time, a cicatrix one inch below the border of the left orbit. No irregularity of the orbital edge could be detected. Pressure on the globe caused no pain. The movements of the eye were normal, and the pupil active. The iris had a slightly greenish hue. An extremely vascular growth was seen with case. This appeared to fill the fundus. After consultation, it was deemed advisable to enucleate the eye. This was done, the wound healing promptly. Examination showed that there had been cyclitis with inflammation of the vitreous, with the production of a mass of inflammatory tissue, extending across the eye behind the lens, forming a perfect septum. The retina was totally detached, and the choroid was partially detached. There was, also, marked hypertrophy of the tissues at the base of the orbit. It was thought that the original process had been an injury to the floor of the orbit.

[1] Continued from page 111.

PROLAPSE OF THE LACHRYMAL GLAND.

Dr. Noyes also reported the case of C. S., aged twenty years, who consulted him on account of a swelling in the upper lid of the right eye. This had been growing for nine years. It could be freely moved over the globe, and moved with movements of the eyeball. There was no history of injury or of inflammation of the eye. The mass was removed, and found to be a displaced lachrymal gland. The removal has been followed by no unpleasant effects. Four cases of displacement of the lachrymal gland are on record.

OPERATION FOR THE RELIEF OF ENTROPION OF THE LOWER EYELID.

While, in theory, the operations for the relief of this condition are very simple, yet, in practice, they often fail to accomplish the desired end. The author described an expedient which he had employed four years ago. He excised a piece of skin below the border of the lid, and then dissected up a flap, leaving an open wound. He next freshened a spot on the outer border of the lower lid, taking out a piece of conjunctiva. He then turned the flap upward, and attached it to the freshened surface. This little flap served to hold the lid in a position of eversion. In one week the stitches were removed. The patient then disappeared, and was not seen for four years. It was then found that the lid remained in a natural position. The little bridge of skin still was present, and under it there was a sinus, through which a probe could be passed. The piece of skin was divided, and the result was perfect.

DISCUSSION.

Dr. Samuel Theobald, of Baltimore. In connection with the case of glioma, I would mention one that has gone nine-and-one-half years without a return. The only weak point in the case is that no microscopical examination was made. The microscopical appearances were, however, characteristic. The operation was done when the boy was six years of age. The boy is still perfectly well, and there is no suggestion of the return of the disease.

Dr. H. Knapp, of New York. Until lately, I have held the view that there was such a thing as the permanent cure of glioma, but now I am very doubtful if this is ever accomplished. There are exceptional cases, which do not terminate fatally until ten or fourteen years after operation. They then die from a return of the local disease, or else from a generalization of the condition. Graefe said that all of these cases died.

Dr. J. S. Prout, of Brooklyn. I have had one case of plastic exudation in the eye of a child, which went on to rupture of the eyeball and the death of the patient. I believe that life might have been saved if the eyeball had been removed.

Dr. B. E. Fryer, of Kansas City. In the diagnosis of small intra-ocular tumors, I have, in several in-

stances, derived much advantage from the use of the electric light.

DR. H. KNAPP, of New York. In the illumination of those eyes which are blind, I have used sunlight. The light is admitted through a hole in the shutter, and thrown into the eye by a large concave mirror. This is of advantage in the diagnosis of glioma and of sarcoma, where the fundus is often very dull.

DR. EMIL GRUENING, of New York. I have seen two cases in which there has been an apparent immunity from the return of glioma. The first case was operated on in 1875. The patient was a girl, five years of age. The optic nerve was not involved. The girl is still under observation, and in perfect health. The second case, a child one year old, was operated on May, 1880. It was a case of true glioma, with no involvement of the optic nerve. The child is still perfectly healthy. Both of these patients have been wearing artificial eyes since the operation.

DR. JOHN GREEN, of St. Louis. I have found most of the operations for entropion of the lower lid unsatisfactory. I have, in a general way, followed Panas's recommendation of making an incision below, and bringing the lid down by the use of sutures. I have extended this operation by the following procedure: After inserting the sutures, I make a cut a little inside of the border of the lid, carrying it through the whole thickness of the tarsal fibrous tissue. When this is done the sutures are much more effective, and I find that there is no tendency for cicatricial contraction to occur in the process of healing. The results obtained by this method have been eminently more satisfactory than those obtained by any other procedure.

DR. EMIL GRUENING, of New York. In the treatment of entropion of the lower lid, I have employed the method of Hotz. I have exaggerated this a little by passing the sutures through the whole thickness, not only through the orbital tarsal aponeurosis, but also through the conjunctiva. I have now under observation six cases which have been operated on during the last six years, and the result has been satisfactory.

A PHENOMENAL PULSATION OF THE INTERIOR OF THE EYE,

by DR. W. F. MITTENDORF, of New York.

The patient, fifteen years of age, came under observation for asthenopic trouble. He showed no signs of disease. The tension of the eye was normal, and the fundus was normal. There was no pulsation of the arteries or veins, but pulsation could be induced by pressure. A short distance above the disk, there was a grayish-white band, stretching from one vein to another, and looking like a little sac filled with fluid. In the middle, this band presented a little point. This band presented a distinct pulsation, which corresponded with the cardiac pulsations. The patient was seen a number of times, and the appearance was always the same. A little higher up, and more to the nasal side, there was a similar band connected with an artery. This did not pulsate, except when pressure was made. It was thought that the band was composed of connective tissue, which was thrown into vibration by the meeting of the vibration of the two veins with which it is connected.

DISCUSSION.

DR. EDWARD JACKSON, of Philadelphia. I recently saw, in a case that presented no spontaneous pulsation, a little band extending from the perivascular sheath, which was thrown into vibration with each radial pulsation. This condition occurred in both eyes.

INCREASE OF BLINDNESS IN THE UNITED STATES,

by LUCIEN HOWE, M.D., of Buffalo.

Attention was called to the fact, that while the population during the ten years from 1870 to 1880, increased at the rate of 30 per cent., blindness during the same time increased over 140 per cent. By means of a diagram this percentage of increase in each State separately, was shown. The statistics also show that blindness increased in an almost constant ratio from north to south in the United States, and that it decreased in the same way from east to west. This was also shown by colored maps. The cost of sustaining this army of over fifty thousand blind was estimated on the lowest basis of cost, and of wages which would have been earned, at over sixteen million dollars in 1880, or over twenty-five million in 1887. As for the causes, contagion was found to exercise the most important influence; this was found by a special examination made for the purpose of 128 pupils at the Batavia asylum for the blind, by the statistics collected by Magnus, and by the record of over forty-eight thousand cases treated at the Manhattan Eye and Ear Hospital. Immigration was also considered as an important factor, in view of the large number of contagious diseases of the eye introduced every year into the country, and the laxity or absence of quarantine regulations regarding them. As for the prevention, suggestions were offered:

First, As to the care of new born children.

Second, The isolation of suspicious cases in residential schools and other institutions, even for adults also.

Third, The instruction of the public as to the advisability of guarding against contagious forms of disease.

Finally, It was advised that the entire matter be referred to a committee to examine again the statistics, and report more complete methods for the prevention of blindness.

DISCUSSION.

DR. SWAN M. BURNETT, of Washington. I have been much interested in the statistics of Dr. Howe, particularly in those with reference to the greater percentage of blindness in the southern portions of the United States as compared with the middle and more northern portions. This brings up the important question of the influence of race. The larger part of the population of the South is, of course, negroes, and the larger part of the blindness must be among that race. It has been my experience that negroes do not suffer to any degree from trachoma. In a study of several thousand cases of eye troubles among the negroes, I have found only one genuine case of trachoma and that occurred in a mulatto. The conjunctival diseases, which in other races cause a large part of the blindness, must be thrown out in considering the negro. The negro, however, suffers much more from scrofulous disease of the eye, particularly of the cornea, than do the white race. Negroes also suffer largely from ophthalmia neonatorum, and many cases of blindness due to that cause have come under observation.

DR. W. F. MITTENDORF, of New York. I am not surprised to hear that blindness in the United States is increasing. I think that the most prolific cause of this is the overcrowding of young persons in

institutions. An examination of a large institution in the neighborhood of New York has shown a large number of contagious ophthalmic cases in that institution not known, or neglected. In our large dispensaries we meet almost weekly with persons who have become blind from neglect and from contracting diseases of this kind in such institutions. It is very difficult to get an idea of the exact number of blind persons. The great majority of blind children are not counted in these statistics. They are kept at home and provided for there. One of the most important things is to stamp out these diseases in large institutions, and the best way to do this is to prevent overcrowding. Instead of placing the children in large buildings, they should be sent to the country and placed in small numbers in cottages.

Dr. Peter A. Callan, of New York. The whole question turns on this, what can we do? We are very backward in that respect. In London they have a Society for the prevention of blindness, which does good work. The spread of the disease is often due to neglect and often to the use of improper applications in ophthalmia neonatorum on the part of the mother or nurse. Ought we not in every State to organize societies and instruct the people what they should do and what they should not do?

Dr. Myles Standish, of Boston. It has been my experience that the most troublesome cases of trachoma and the like occur in persons who have been in this country only two or three weeks. When they arrive in the country the disease is usually at its height and they are in a condition to spread the affection among those with whom they come in contact.

In connection with this matter, Dr. Howe offers the following:

Whereas, The census reports indicate that there has been an increase in the number of blind in the United States, more than four times as great as that of the total population, and

Whereas, An inquiry as to the causes of this, shows that it is largely due to contagious diseases of the eye, therefore

Resolved, That a committee of three be appointed to examine further as to this apparent increase, and recommend means for its prevention.

Resolved, That the President of the United States and the Secretary of State be respectfully requested to furnish this committee with whatever letters or other recommendations may be necessary to further their investigations in this country or elsewhere.

Resolved, That the officials in charge of residential schools and similar institutions also be requested to assist the committee to any extent in their power.

These resolutions were adopted, and the President announced Dr. Lucien Howe, of Buffalo, as chairman of the committee, the other members to be appointed subsequently.

(To be continued.)

— At the meeting of the American Dental Association, held at Niagara Falls, August 4th, the following officers were elected: President, Frank Abbott, New York; First Vice-President, C. R. Butler, Cleveland, Ohio; Second Vice-President, F. S. Waters, Baltimore; Corresponding Secretary, F. A. Levy, Orange, N. J.; Recording Secretary, G. H. Cushing, Chicago; Treasurer, G. W. Keeley, Oxford, Ohio.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 11, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 Boylston Street, Boston, Mass.

ACADEMIC AND PROFESSIONAL COURSES OF STUDY.

Some months since we referred to a proposition made by the Medical Faculty a year ago, to the Academic Council of Harvard University, relating to a modification of the academic course in the interest of the professional schools and the graduate department. It was then shown that, with the raising of the standard of admission, the development of elective studies, the relaxation of the former parental oversight of the students, the age of graduation had been and was steadily advancing, until a point had been reached where the efforts of the professional school, and especially of the Medical School, to encourage an academic course as a preliminary to, or to increase the length of their own courses of study, were seriously antagonized. So seriously in the estimation of not a few friends of the Medical School, that an average age of graduation from the Academic Department of twenty-three, or even of over twenty-two years, constituted an absolute barrier to that school's establishing a compulsory four years' course as far as support from the College of its own university was concerned.

Since the proposition of the Medical Faculty was submitted, the Committee of the Council, to whom it was referred, have held five meetings, at which all the members were present, and a very full and free oral discussion of the subject took place. Moreover, most of the members presented in carefully prepared written papers their views on the merits of the various plans proposed, or suggestions as to the best manner of meeting the difficulties which had presented themselves.

A report, privately printed, publishing these in the form of appendices, shows that the committee, representing different departments and interests of the University, find themselves unanimously of the opinion that it is desirable to enable Harvard students to begin their professional studies one year earlier than is possible under existing arrangements. "Any general plan which may be adopted for bringing about this result must effect a diminution in the amount of

undergraduate training, and a corresponding increase in the amount of graduate instruction, and in order to secure the best results from a change of this sort, the Committee recommend an alteration of the University organization, which they also regard as in itself desirable in the interest of higher education: namely, the consolidation of the instruction in the College, the Graduate Department and the Scientific School, under the control of a single Faculty. The Committee at the same time think it of great importance for the success of such a reorganization that the scholarships now granted to undergraduates be made available also for students in the Graduate Department."

We understand that the members of the Committee were pretty evenly divided in their preferences as between two of the plans proposed for securing the changes which all concurred in deeming desirable. In order, therefore, to inaugurate these changes the Committee agreed to recommend to the Council the adoption of the following votes:

(1) That in the opinion of the Academic Council it is desirable that the instruction in the College, the Graduate Department and the Scientific School, be placed under the control of one Faculty.

(2) That in the opinion of the Academic Council it is highly important that the College scholarships be made available for all students under the control of this Faculty.

(3) That, with a view to lower the average age at which Bachelors of Arts of Harvard College can enter the professional schools and the Graduate Department, the College Faculty be requested to consider the expediency of a reduction of the College course to three years, by one or the other of the following plans:

(*a*) By giving the degree of A.B. at the end of the present Junior year.

(*b*) By putting the terms of admission to the Sophomore Class on a par with those prescribed for admission to that class in the better New England colleges, and ultimately abolishing the Freshman year by a plan similar to that suggested by the Dean of the College Faculty.

It will be remembered that the original proposition of the Medical Faculty was, that the degree of A.B. be granted to all undergraduates subsequently taking the longest course of study offered at the professional schools after three years' attendance (at the end of the Junior year), in the Academic Department: the professional degree and that of A.B. to be given simultaneously at the end of the professional course, it being understood that the requirements of each should have been fulfiled. A subsequent modification suggested to this proposition was that the degree of A.B. be given at the end of the first year of the professional course, instead of at the close of that course.

We are glad to be able to report the prospect of a favorable action upon this proposition by the Academic Council. The changes proposed are really nothing more than the legitimate and necessary outcome of the previous changes which have been made of late years in the Academic course. The recognition of the embarrassments involved in the present situation is the important thing, the precise form which shall be given to a modification of the existing situation is of less consequence.

THE CAUSATION AND TREATMENT OF CHOLERA MORBUS.

IF epidemic cholera be due to the local action in the intestinal canal of a special microbe, as is generally held by those who accept the germ theory of infectious diseases, it would seem that cholera morbus, which so resembles the former disease in its essential characters, might also be due to a microbe, though of a less malignant nature. Such considerations have led Liebermeister to reckon cholera nostras among the microbic diseases, although there is no evidence that it is *infectious*, at least, in the way in which this term is commonly understood. "It bears the same relation to true cholera," says Liebermeister, "that varicella bears to small-pox." The discovery of Finkler and Prior, who claim to have found in the dejections of patients suffering from cholera morbus bacilli, bearing a strong resemblance to the comma bacillus of Robert Koch, would have great importance if it should be hereafter shown that these bacilli are constant, and have an etiological relation to the disease in question.

Certainly, however, in the present state of medical science, there is not sufficient warrant for classing this so-frequent malady of hot weather among the infectious or bacillary diseases. Its causal agent seems much more likely to be a poisonous ptomaine generated by the decomposition of food — a poison which acts as an irritant to the gastro-intestinal nerves, paralyzing the vaso-motors, and thus giving rise to an excessive outpouring of serum, to vomiting and diarrhœa. This view is favored by the sudden onset, the rapid development of symptoms, and the dangerous collapse.

The experience of practitioners generally corroborates the above view, that attacks of cholera morbus are ordinarily caused by some fermentative change in the ingesta, and here it is principally the quality of the ingesta that is operative, unripe fruits or vegetables, and food that is relatively indigestible (baked beans, fried clams, berry-pie, etc.) being most likely to provoke an onset. The patient, on being interrogated, will generally refer his sickness to some indiscretion in the quality of the food which he has eaten. It is true, also, that eating to excess, even of simple food of relatively easy digestion, may be followed by an attack, and it is probable that sometimes the free drinking of ice-water may have the same result. What one may eat at one time with impunity, may, at another, when, by heat or overwork, the organism is enfeebled, have disastrous effects.

All are agreed that the most powerful predisposing

cause of cholera morbus is hot weather. Excessive heat exhausts the nerve-centres, depresses the vital tone, and thus renders the organism less capable of reacting against the exciting causes of disease, while at the same time it increases the rapidity with which perishable articles of food decay and become injurious. This is well shown in the behavior of a kindred disease, cholera infantum, under the influence of dog-day weather, and every physician has witnessed both the amelioration accompanying the advent of cooler days, and the exacerbation which attends the prevalence of a high temperature. The quality of the atmosphere, too, has much to do with promoting or retarding the manifestations of all forms of cholera, which, certainly, are greatly favored by damp, as well as hot air, and by air contaminated by noxious emanations. It will not do, also, to omit the influence of drinking-water. The offensive exhalation from a filthy alley, which had been recently cleaned, was the exciting cause of a fatal epidemic in a London school, and Levier recounts an epidemic caused by the drink-water during the winter in Berne.[1]

In the treatment of cholera morbus, prophylaxis is of the first importance. He who would avoid attacks must live temperately, and shun over-heating and depressing emotions. A robust dietary and "high living" when the digestive and assimilative powers are relatively enfeebled is irrational, and sure to result in mischief. But, unfortunately for the patient, the physician's services are generally sought at a time when something besides prophylaxis is demanded. The tableau is sufficiently familiar: there are cramps, colic, vomiting, purging, and collapse. Here, as has long been known, there is one remedy that is sovereign, that may almost be regarded as specific, and that is opium.

The late Dr. George B. Wood used to give, every half-hour or hour, a powder containing one-sixth-of-a-grain each of calomel and opium. For the opium, was sometimes substituted an equivalent dose of sulphate of morphia, and his practice and teaching was largely followed. Very gratifying results were generally obtained. In the course of two or three hours, the painful and dangerous manifestations were allayed. The stomach would generally retain the opiate, placed dry on the tongue, and washed down with a fragment of melting ice. All drinks were for a time strictly forbidden, little bits of ice being permitted from time to time. Then, as the vomiting subsided, mild diluents, and finally, nutrients were gradually allowed. Revulsives to the surface were always ordered, but it was seldom found necessary to begin with an evacuant treatment.

While the past twenty-five years have not much improved on this mode of treating cholera morbus, doubtless the substitution of the hypodermic injection of morphia and atropia has been a real gain. One centigram of morphia, with one-half milligram of atropia, is generally sufficient. It is, in fact, seldom found necessary to repeat the injection, which, if made the second time, should be made without the atropine. Much more prompt and thorough relief is obtained by this plan than by the old calomel and opium treatment. Calomel is still given, both in minute and in full doses, by some practitioners, but cases seem, in our judgment, to do as well without it. Bismuth, hydrocyanic acid, carbolic acid and alkalies are sometimes useful adjuvants. The heart's action may be sustained, and collapse combated, by subcutaneous injections of ether or whiskey, but, as Johnston remarks, "the morphia will be the best and quickest stimulant which can be used; it will, therefore, be useless in most cases to administer brandy, camphor, chloroform, or other remedies of that sort."

Cholera morbus has been known from the most remote times. Hippocrates and Galen well describe the congeries of symptoms, but Sydenham's description of the epidemics in England, 1669–72, is the earliest account of the disease in modern literature, and it was he who gave it the name cholera morbus.[2]

MEDICAL NOTES.

— *Science* has had a "*symposium*" of milk; we may add of distillery milk or "swill milk." The sanitary authorities who responded to the request of the editor for their opinion as to the healthfulness of milk from cows fed on brewery grains, evinced a surprising variety of opinion. A majority naturally object to such milk, but quite a number consider the case against it as "not proven," and ascribe such ill results as appear to have followed its use to insanitary conditions prevailing in the stables and associated with the care of the milk.

— A writer in *Harper's Bazaar* makes a pretty close diagnosis for a layman, as to what ails the modern girl, at least a good many of her. It is well deserving of record as an *indicatio causalis* in the disease which is so often the despair of the doctor. "The modern girl hardly knows what she wants, whether it is the higher education, an æsthetic wardrobe, love or fame. She plays tennis and progressive euchre, and flirts and does Kensington work and reads Herbert Spencer, and very often writes; she dabbles in music and talks theosophy, and if there are more things in Heaven and earth than are dreamed of in her philosophy one questions what they can be. Withal, she is as restless as the wind. She does not love the quiet of home; she lives on excitement; she goes to Europe, to the springs, the mountains, the theatres, the receptions, if she can get there, or to the modiste; she can always fall back upon clothes as a diversion, and, when everything else fails, she has the nervous prostration and a trained nurse. In fact, the chief trouble with the modern girl, be she rich or poor, is that she either does too much, keeps her nerves on the strain, and by and by goes to the other extreme, and does literally nothing but consume drugs, talk of her ills, and consult the Christian scientists, or she has no real interests, fritters away her time in shallow pursuits,

becomes pessimistic and dyspeptic, dissatisfied with herself and all the world, cries, and questions if life is worth living, and feels especially blue on holidays. The remedy for all this is, perhaps, an object in life; those who are well and unselfishly occupied do not question if life is worth living; they know it is; and whether they are busy in the shoe factory, behind a counter, at the fireside, in the kitchen or the dining room, so long as they are busy and not shirking or reaching forward for something more congenial, and neglecting present duty, their minds are at rest and uninvaded by despondency. One of the best remedies for depression of spirits is the effort to bestow happiness; it has been known to prove effectual when all other methods have failed, when novels and new gowns and cod-liver oil and bovinine and bromide, when admiration and flattery, are no more serviceable than an abracadabra or any heathen spell. Melancholy or other ills of this nature are the direct result of a too strong egotism, and an absorbing interest in others is a safe and agreeable medicine, and is usually the last thing a modern girl tries."

NEW YORK.

— Special efforts are at present being made by the Health Department to prevent, as far as possible, the excessive crowding of tenement-houses, which is the source of so much disease and mortality. The inspectors have, consequently, been ordered to report all cases where the overcrowding is due to the fact of boarders being lodged, in addition to the members of the family, where there are not four hundred cubic feet of air for each adult, and two hundred for each child under the age of puberty, and where the ventilation is insufficient. A number of houses in the down-town streets have also been ordered to be vacated, as unfit for human habitation.

— At the last meeting of the Board of Health sixty-one physicians were reported for failing to report cases of contagious diseases within the time prescribed by the Sanitary Code, and such of them as are unable to present a satisfactory excuse will be prosecuted. On motion of Commissioner Bryant, the following physicians were invited to inspect and make criticism upon the arrangement and management of the Reception, Willard Parker and North Brother Island Hospitals, where those suffering from contagious diseases are cared for: E. G. Janeway, J. O'Dwyer, Stephen Smith, C. R. Agnew, A. Jacobi, and D. M. Stimson.

— On the 4th of August, Dr. Edson, of the Health Department, with the aid of the food inspectors and police, seized over a ton of decaying fruit and vegetables on the east side, down town.

— Dr. Leo Sommer, a Hungarian investigator, who had received the permission of the Mayor and the President of the Board of Health to experiment upon the dogs in the city pound with hydrophobic inoculations, has been prevented from carrying out his inoculations by the agents of the Society for the Prevention of Cruelty to Animals, who claim that, under the law as it now stands, such experiments can be performed only under the authority of some regularly incorporated medical college or university in the State, which authority Dr. Sommer does not possess.

— Since the erection of the Brooklyn Bridge, a number of individuals have intentionally jumped from it into the river below, but, on August 1st, a young man who was assisting some workmen engaged in painting the iron-work accidentally fell from the bridge. He struck the water, one hundred and twenty feet below, chest-first, and though he was unconscious when rescued, he soon recovered his senses under appropriate treatment. He was taken to the Chambers Street Hospital, where it was ascertained that he had received a fracture of the sternum, but beyond this and one or two slight bruises, he was apparently uninjured. According to the last accounts, he was doing perfectly well.

Miscellany.

SPONTANEOUS RUPTURE OF THE CORD.

RUPTURE of the umbilical cord in labor is a comparatively rare accident. It has occasionally occurred when a woman has been surprised by the expulsion of the child while she was standing, the child falling to the floor, for a sudden force less than the weight of the child will cause the cord to give way.

But can there be a spontaneous rupture, if the woman be delivered in bed? This is a very important question in medical jurisprudence. For example, if a mother be found with a recently born child that is dead, the death having been caused by the bleeding from a ruptured cord, that rupture occurring at the umbilicus, or at some other part, one might hastily conclude that the injury was done by the mother or by some one else, and its purpose was to kill the child. Some cases, however, reported by Budin, in the *Annales d' Hygiène Publique* for June, 1887, prove that the conclusion might be quite unjust; in other words, spontaneous rupture of the cord may occur where there has been no interference whatever, and the mother was delivered in bed. The number of cases of this accident presented by Budin is four, the first by Schatz, the second by Dupuy, and the other two occurred in his own service in La Charité. In neither of Budin's cases was there any relative or absolute shortness of the cord, and it was of usual size; the rupture occurred solely from the utero-abdominal contractions which expelled the child. — *Medical News.*

AN UNUSUALLY RAPID CASE OF GRAVES'S DISEASE.

Dr. J. MICHELL CLARKE recently reported to the Bristol Medico-Chirurgical Society a case (also described in the *Practitioner* for May) of Graves's disease in a girl of eighteen that proved fatal in six weeks. She came of a healthy family, commenced to menstruate at the age of fourteen, and enjoyed good health until June, 1886. During a menstrual period she then experienced violent palpitation of the heart, frontal headache, and pain in the præcordial region with

nausea and vomiting; the next period was regular and without these symptoms. On August 4th the palpitation returned, though not so severely; but she noticed also that her eyes were becoming prominent, that her throat was larger, and that she was losing flesh without any obvious cause. A fortnight later she was admitted into the Bristol Infirmary, when she presented all the symptoms of a typical case of Graves's disease. There was a great enlargement of the thyroid, and a thrill could be felt in it; the eyes were very prominent; von Graefe's lid-sign was present; and the heart was beating very rapidly, with a forcible impulse and a blowing murmur at the base. There is no mention of sweating or of tremor. At first she went on well, taking arsenic, but then vomiting, and later diarrhœa set in, and she rapidly lost flesh and eventually died on September 13th, the heart's action towards the last having been extremely rapid, the emaciation great, the gums bleeding, and the hair falling out. No changes were found in the nerve centres.

Correspondence.

THE OUNCE TROY AND THE OUNCE AVOIRDUPOIS.

TRENTON, N. J., August 2, 1887.

MR. EDITOR,—In your issue of June 23, 1887, has just come to my notice the very interesting report by Dr. Morse, of Clinton, of a case in which a large quantity of sulphate of morphia was ingested followed by recovery; and it presents a good opportunity to call attention to a very common error, that which supposes a wholesaler's one-eighth ounce of morphia to be equal to one ounce Troy.

One ounce Troy (℥) is equal to one ounce avoirdupois and 42.5 grains Troy over and the one-eighth bottles of the wholesalers contain not one ounce but about 54.7 grains Troy; and if Dr. Morse's calculations are made from the one ounce basis, his patient took, not 51 grains of morphia but about 45.7 grains.

The fact has escaped the attention of many of my friends, and it will not be amiss to call attention again to it. Yours truly,

HORACE G. WETHERILL, M.D.

ANOTHER SHORT CUT INTO MEDICINE.

BROOKLYN, N. Y., August 6, 1887.

MR. EDITOR,—Seeing a communication in your columns headed "An M. D. in Nine Months," reminds me of a similar instance that happened not a thousand miles from this city. The first course of lectures in this instance was taken at Ann Arbor, and the whole course was less than one year. The same college let a man through a few years ago, out of pity, after having decided that he was incompetent, because he attempted (?) suicide.

I for one think it is high time for some of our Medical Colleges to turn over a new leaf. Your truly,

READER.

REPORTED MORTALITY FOR THE WEEK ENDING JULY 30, 1887.

Deaths reported 3,102: under five years of age 1,472; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1,109, lung diseases 111, consumption 290, diarrhœal diseases 877, diphtheria and croup 69, typhoid fever 48, measles 30, whooping-cough 30, cerebro-spinal meningitis 17, scarlet fever 14, malarial fevers 14, puerperal fevers five. From measles, Boston eight, New York six, Philadelphia five, Brooklyn and Pittsburgh three each, Baltimore two, District of Columbia, Lowell and Newton one each. From whooping-cough, New York and Philadelphia eight each, Milwaukee four, Baltimore and Pittsburgh three each, Brooklyn, Boston, New Orleans and Fall River one each. From cerebro-spinal meningitis, New York, Milwaukee, Fall River and Somerville, three each, Philadelphia, Portland, Pittsburgh, Lowell and Haverhill one each. From scarlet fever, New York four, Philadelphia and Brooklyn three each, Boston, New Orleans, Pittsburgh and Lowell one each. From malarial fever, New York seven, Brooklyn four, Charleston two, District of Columbia one. From erysipelas, New York two, Boston and Portland one each.

In the 23 cities and greater towns of Massachusetts, with a population of 1,069,576 (population of the State 1,941,465) the total death-rate for the week was 32.86 against 27.41 and 26.37 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending July 16th, the death-rate was 20 7. Deaths reported 3,660: infants under one year of age 1,305; acute diseases of the respiratory organs (London,) 188; diarrhœa 497, measles 152, whooping-cough 132, scarlet fever 50, fever 25, diphtheria 23, small-pox (London) one.

The death-rates ranged from 13.6 in Portsmouth to 31.1 in Preston; Birmingham 17.9; Blackburn 18.8; Bradford 17.4; Hull 16.2; Leeds 22.4; Liverpool 20.7; London 22.0; Manchester 24.5; Newcastle-on-Tyne 22.9; Nottingham 14.7; Sheffield 18.3; Sunderland 17.3.

In Edinburgh 20.0; Glasgow 17.5; Dublin 27.9.

The meteorological record for the week ending July 30, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JULY 30, 1887, TO AUGUST 5, 1887.

SUTHERLAND, CHARLES, colonel and surgeon. Leave of absence extended one month. S. O. 174, A. G. O., July 29, 1887.

FRYER, B. E., major and surgeon. Relieved from further duty at Fort Lowell, Ariz. S. O. 176, A. G. O., August 1, 1887.

MCCLELLAN, ELY, major and surgeon. Detailed as member of a board of survey to meet at the Medical Surveying Depot, St. Louis, Mo., on August 1, 1887. S. O. 173, A. G. O., July 28, 1887.

BROWN, HARVEY E., major and surgeon. Relieved from duty in Department Missouri, and ordered to Jackson Barracks, La., for duty at that post. S. O. 174, A. G. O., July 29, 1887.

GARDINER, JNO. DE B. W., captain and assistant surgeon. Granted leave of absence for one year on surgeon's certificate of disability. S. O. 177, A. G. O., August 2, 1887.

DIPHTHERIA AND DEFECTIVE SEWERAGE IN THE MASSACHUSETTS HOMŒOPATHIC INSANE ASYLUM AT WESTBORO.

THE daily papers have made public the fact of the death from diphtheria of six persons, inmates and attendants at the Homœopathic Insane Asylum at Westboro, as well as the serious illness from the same disease of eight or more other persons, who did not die. Besides this, it is said that many others suffered from sore throat. As we learn from the *Worcester Daily Telegram*, the plumbing of the institution has been found to be in a deplorable condition. It was put in, last year, by T. H. Duggan, of Boston, a member of the Boston City Government. The Building Committee, of the Trustees, consisting of two persons, one of whom was a woman, reported last October: "The Building Committee have given close personal attention to every detail of the work, having visited the hospital thirty-nine times during the year, fifteen of which visits occupied the entire day." The *Telegram* says that some of the joints in the plumbing were not leaded at all, putty being used in place of lead, and others were of a most imperfect character. It adds that the attention of the authorities was called at the time to the unsatisfactory character of the work, but it was, nevertheless, accepted.

Shortly after the sewers had been used, foul smells could be detected quite plainly. The attendants complained of scents in the closets and water-sections. One of the kitchen employees said, in February, that she could smell sewer-gas in her sleeping-room. Later on, she was taken sick with diphtheria. The sewage was conducted into a meadow about fifty rods from the institution, and during the heavy north-east storm, the latter part of May, the scent was wafted back to the building. It is said that the city of Boston has come down upon the institution for polluting its water-supply, and that the whole system will have to be changed, and run from one hundred and fifty to two hundred rods the other way.

The same paper adds that the contract for the driven wells required that they should stand a constant pumping of thirty days and thirty nights. On March 17th, when the ground was full of water, and water was standing on top of the ground, the test began, and the wells, of course, stood it. In June, the engineer, it is claimed, was obliged to run the pumps with a very slow stroke, to keep them from pumping air.

Boston plumbers are now at work, and will probably occupy the greater part of the summer in making the repairs, which will involve a very heavy expense.

LAPAROTOMY FOR PUS IN THE ABDOMINAL CAVITY, AND FOR PERITONITIS.[1]

BY JOHN C. IRISH, M.D., OF LOWELL.

It is only very recently that cases of septic peritonitis, and of pus, free or encysted, within the serous membrane of the abdomen, have been systematically treated by abdominal section and drainage. Within the past three or four years, however, quite a number of such operations have been reported, particularly by those engaged in abdominal surgery. But this number is still so small, and the indications for operative interference so indistinctly defined, as to lead me to hope that a report of additional cases will be interesting.

The consideration of pelvic abscesses might properly come within the scope of this paper, as a portion of them, at least, are intra-peritoneal collections of pus. Many of them, too, have been treated by abdominal section and drainage. A portion of these operations have been, undoubtedly, laparotomies, according to the general acceptation of this term, while, in other cases, the operation has not differed from the opening of other abscesses that have pointed externally. I shall omit all discussion of pelvic abscesses, with the exception of those rare cases in which the pus has escaped into the cavity of the peritoneum.

To the treatment of retro-peritoneal, peri-typhilitic, and other extra-peritoneal abscesses, I wish to call your attention only in the event that they have become intra-peritoneal by escape of pus into the peritoneal cavity — an accident that is far more frequent with these than with the pelvic abscess.

As an introduction to the consideration of my subject, I desire to present, with as little detail as possible, the three following cases. Two of them are illustrations of the circumscribed peritoneal abscess; the third is an example of the irruption of pus, that had formed elsewhere, into the peritoneal cavity.

Case I. Under the care of Dr. Lane, of Billerica, to whom I am indebted for the following history: J. L., a young man; age nineteen. At the time of my first visit, April 3, 1884, he was suffering from a general condition of fever. Pulse 100, temperature 102°; bowels constipated and tender upon pressure. This condition continued about ten days, save a fluctuating temperature. Then the bowels began to enlarge, with increasing tenderness on the left side of abdomen, and with decided dulness on percussion. From this time, the pain, tenderness, and fulness of the left side steadily increased. The pulse and temperature varied greatly from day to day, the former ranging from 100 to 130, the latter from 100° to 104°.

May 3d, I saw the patient with Dr. Lane. At this time, there was marked prostration from general septic poisoning. The pulse 120, temperature 103°. Over the left anterior portion of the abdomen, extending about two inches to the right of the umbilicus, and distending the parietes, could be felt a fluctuating mass, uniformly oval, and dull on percussion. An abdominal incision three inches in length was made, through which escaped about three quarts of an odorless, purulent liquid. An examination through the incision demonstrated the parietal peritoneum, and, with the hand in the pus-cavity, there could be felt, on the right side, the agglutinated coils of intestine and the fibrinous partition wall that separated the abscess from the remaining portion of the peritoneal cavity. Although neither the previous history of the case, nor our examination revealed the cause of the abscess, yet its intra-peritoneal origin was clearly shown.

After the cavity had been thoroughly washed out with a mild antiseptic solution, a drainage-tube was inserted, and the usual dressings applied. In a few days the pulse and temperature became normal, and the patient went on uninterruptedly to recovery, which was complete in two months after the operation.

Case II. N. P., Lowell, man, aged twenty-six. A patient of Dr. Chadbourne. In the latter part of December, 1886, an abscess, not due to any appreciable cause, pointed just below Poupart's ligament on the right. This was opened with the bistoury, and about eight ounces of pus escaped. The pus track extended over the os pubis, and deeply within the pelvis. The abscess was evidently extra-peritoneal, and originated somewhere in the pelvic cavity.

Three months later, there appeared on the left side a moderate distension of the abdominal walls. Over a well-defined space were dulness and fluctuation, but no tendency at any point to a spontaneous opening of the abscess appeared.

An incision three inches in length, and four inches to the left of the median line, gave exit to about three pints of a thin, offensive pus. The cavity was washed out, a glass drainage-tube inserted, and the remainder of the wound closed with sutures.

The patient has made an entire recovery, so far as the peritoneal abscess is concerned. From the pelvic abscess, a slight discharge of pus still continues along the fistulous track.

In attempting to solve any possible doubt as to the intra-peritoneal origin of this second abscess, I explored with my hand the pus-cavity, but so profuse a hæmorrhage from the partition walls followed my manipulations, that I was obliged to desist.

I concluded, however, that its site was intra-peritoneal, and have so classed it for these reasons: Because the anterior boundary seemed to be the parietal peritoneum, thickened and covered with a lymph and fibrinous deposit; because the contained fluid had the gross appearances usually found in the encysted purulent effusions of a localized peritonitis; and because the hæmorrhage that I mentioned would readily come from intra-peritoneal adhesions, but would not certainly be expected from the walls of an extra-peritoneal abscess.

Case III. This patient was under the care of Dr. Trueworthy, of Lowell, who has kindly prepared for me the following report of the case up to the time of operation:

Mrs. D., of Lowell, age twenty-five. August, 1881, was thrown from a carriage, and dragged a considerable distance. After the accident, she suffered from great pain and soreness in the lower part of the bowels, and from a menorrhagia, that continued about five weeks. Mrs. D. was married in the fall of 1881, but has never been pregnant. In July, 1882, she had an attack of pelvic cellulitis, from which she recovered slowly and imperfectly. From this time her menstruation was irregular, and her general health somewhat impaired. April, 1885, she had an attack of

[1] Read before the Massachusetts Medical Society, June 7, 1887, and recommended for publication by the Society.

perimetritis, that continued with varying severity till July 10th, when I saw her for the first time during this illness. The uterus was enlarged and tender on pressure. A solid mass occupied the posterior cul-de-sac. Over the lower portion of the abdomen, there was a general feeling of fulness. The bowels were slightly distended, and the patient complained of severe pain at the lower part of the abdomen. Temperature 103°, pulse rapid. The acuteness and severity of the symptoms, to quite an extent, subsided during the succeeding few weeks, but the pelvic effusion remained and increased. August 20th, Mrs. D. had a chill, followed by a rise of temperature and an increased severity of the general symptoms. Vomiting became frequent, and the swelling in the hypogastric region reached nearly to the umbilicus. Temperature varied, sometimes reaching 104°. The general emaciation and debility had increased up to September 7th.

At this date I was called by Dr. Trueworthy to see Mrs. D. on account of an alarming prostration that had suddenly supervened. The extreme pallor, anxious expression, and feeble pulse of our patient indicated plainly enough that some grave accident had befallen her.

Stimulants were freely administered, and an hour later an incision along the median line, four inches in length, was made. A considerable amount of pus, at least one quart, was found among the coils of intestines and in the dependent portions of the peritoneal cavity. This pus had come from the rupture of a pelvic abscess, whose existence the preceding history of the case has so clearly indicated.

The entire cavity was thoroughly washed with large quantities of warm water. A long drainage tube was carried well down behind the uterus, and the rest of the abdominal wound was closed.

During the operation it became necessary to sustain the patient with frequent subcutaneous injections of brandy. She bore the shock badly, and rallied very slowly. She went on, however, without any incident worthy of mention, to a recovery that was complete six months after.

In considering the surgical treatment of those effusions more or less purulent, occasionally encysted, oftener diffuse, that one finds in the abdominal cavity, their origin and mode of occurrence become an important subject of inquiry: First, we find pus within the peritoneum from the rupture of an ovarian cyst, of a pyosalpinx, of a pelvic abscess, (as the case just described), from perityphlitic, hepatic and other extra-peritoneal abscesses, that have discharged their contents in this direction. Second, more frequently circumscribed peritoneal abscesses are found, which in other words, are localized peritonites with purulent encysted effusions. In a third class of cases we find the pus a product of a diffuse purulent peritonitis.

Therefore, in discussing the treatment appropriate to those cases of pus within the peritoneum, we are compelled to consider also the various forms of peritonitis, since the latter, in the vast majority of instances, stands in a causative relation to the purulent effusion.

By a somewhat hurried search through the recent medical literature within my reach, I have found reported the three following cases, nearly analogous to Case III, of this paper:

CASE I. Operator, Sonnenburg.[2] A large perimefritic exudation had broken into the abdominal cavity, several weeks after the confinement of the patient. A very acute peritonitis was at once excited. Laparotomy, careful cleansing of the peritoneum, drainage, recovery.

CASE II. Mr. Treves.[3] Woman, twenty-one years of age, with a pelvic abscess following gonorrhœa. At the time of operation the abdomen was tense, tympanitic, distended, and painful on pressure. Upon opening the cavity an acute diffuse peritonitis was found. A quantity of semi-opaque fluid, lymph and pus poured out. Pus welled up from the depth of the pelvis. It was found that a pelvic abscess upon the left side had ruptured into the general peritoneal cavity. Drainage was employed. The patient recovered.

CASE III. Lawson Tait, 1883.[4] The summary of this case I quote from the very exhaustive treaty upon "The Surgical Treatment of Peritonitis," published recently by Dr. H. Truc, of Lyons: "Young woman of twenty years. The existence of peritonitis was not doubtful, and there were also signs of intestinal obstruction. A peritonitis from salpingitis is suspected, for the patient received two years before a vielent blow upon the abdomen. Laparotomy; much pus in the peritoneal cavity; pelvic organs agglutinated. No intestinal obstruction. The right fallopian tube contained pus and had been ruptured. Cure. At the end of several weeks there exist some morbid symptoms that are difficult to describe precisely." These few cases, only four, are indeed of very little value in estimating the measure of success that will follow the treatment of extra-peritoneal abscesses that have broken into the peritoneum, by laparotomy and drainage. In another way they have a great value, for they indicate, as clearly as a much larger number could do, the only mode of treatment that offers in this condition any promise of success.

When other bodies gain access to the peritoneal cavity, they excite a peritonitis more or less acute, and usually a pus-forming one. The degree of acuteness and purulence is in direct ratio to the septicism of the foreign material. The rupture of bladder, intestines, liver, or other visceral organs by blows, the penetration of them by wounds or missiles, produces a diffuse septic peritonitis.

Perforation of stomach or bowels by ulcerations, as in gastric ulcer, typhoid fever, or dysentery, is followed by peritoneal inflammation very purulent and septic. In obstruction of the bowels from various causes, in which no perforation has taken place, we often find a pus-producing peritonitis.

In quite a large number of these cases, laparotomy has been done for the cure of the existing lesions, and only indirectly for relief of the peritonitis. Quite a proportion of them have recovered. Thus laparotomy has cured not only the lesion, for which it was made, but the peritonitis as well.

Excluding those cases in which the patient died soon after the surgical interference, the recorded histories show, usually, that the peritoneal inflammation has been entirely relieved or favorably modified by abdominal section and toilet of the peritoneum.

Peritonitis of a very septic character and with rapidly fatal tendency is not infrequently produced by the rupture or degenerative inflammation of ovarian

[2] Arch. Tocol. 1885.

[4] British Med. Jour. 1883.

cyst walls. In 1868, Willshire operated successfully for the removal of a gangrenous cyst that had caused a most formidable peritonitis. A short time before, Keith had also had one of these cases that recovered. And, to-day, I believe it is agreed among ovariotomists that the advent of peritoneal inflammation is a most urgent indication for ovariotomy. A large proportion of the patients in this condition in the hands of Keith, Tait, Homans, and others have recovered. That is, not only the tumor has been removed, but the peritonitis, too, has been cured. I think that no more conclusive proof of the utility of laparotomy for the treatment of peritoneal inflammation could be adduced, than these facts afford.

In localized peritonites with encysted effusions, or, as Mr. Bennett has more happily designated them, encysted peritoneal abscesses, there can to-day be no question as to the propriety of immediately evacuating their purulent contents. The only question can be, in regard to the best mode of doing this. For the purpose of showing the excellent results that have followed the treatment of these abscesses by laparotomy I avail myself of the statistical researches of Dr. Truc:

He gives, somewhat in detail, the histories of ten cases. One of them is that by Dr. Adams, of Framingham; another by Dr. Wilson, of Maryland. To these I have six to add, as follows:

One, by Lawson Tait.[5] Abdominal section was made, and three distinct peritoneal abscesses were found. After the operation the temperature became normal. At the time of writing, the patient had not entirely recovered.

The second, by T. G. Thomas.[6] Laparotomy, drainage, recovery.

The third, by Dr. Watson.[7] A woman, aged fifty-eight; supposed to be suffering from an ovarian tumor. Six quarts of pus escaped through the abdominal incision, and the finger passed into a cavity, at the bottom of which the pelvic organs were felt, covered with a flocculent lymph; while above, the wall of the abscess formed a complete partition between the cavity and the intestines. A drainage-tube was used, and the patient made a good recovery.

The fourth, by Dr. Homans. Case not published. Mrs. S., age twenty-eight. In January, 1882, began to suffer from pain and tenderness of the abdomen, and from slight fever and diarrhœa. These symptoms continued till July, when a fluctuating abdominal tumor was found. Percussion note dull anteriorly, resonant in the right flank, less so in the left.

August 3d, ten pounds of pus were withdrawn with the trochar. August 9th, an abdominal incision, four inches in length, was made, giving exit to eight pounds of pus. Abscess cavity was washed out and drainage-tubes were inserted. The patient recovered in about four weeks after the operation.

The two remaining cases are reported above.

The sixteen cases give these results: — Twelve recoveries, three partial recoveries, and one death.

Peritoneal abscesses, in the past few years, have often been treated by evacuation of their contents with the aspirator. Exceptionally by one or more aspirations a cure has been obtained. Generally, however, the sac refills as often as it is emptied in this way. Several of the above cases were first treated by aspiration, but afterwards it became necessary to make abdominal section and employ irrigations and drainage of the pus cavity.

The lessons, as to the management of encysted peritoneal abscesses, which the histories of these sixteen cases seem to teach, are, that the following treatment is not only appropriate, but that it is almost uniformly successful. The operation should be performed as early as possible, to prevent the progressive loss of strength by the patient and to avert the danger, always present, of a rupture of the abscess walls. An incision, anywhere through the abdominal walls, should be made over the most prominent part of the tumor. This should be done carefully, and all hæmorrhage arrested before the peritoneum is opened. After the purulent liquid has escaped and the pus cavity has been thoroughly irrigated with a mild antiseptic solution, a drainage-tube is inserted and the remainder of the abdominal wound closed. I favor this rather free incision, both to facilitate the escape of pus and to allow a thorough examination of the pus cavity, if this should seem desirable. Should such an examination be made with the hand, great care is necessary, for the partition walls of organized lymph bleed very readily and freely.

Acute diffuse peritonitis not due to the escape of pus or other abnormal material into the abdominal cavity, nor to puerperal sepsis, is less frequent than the localized form that has just now engaged our attention. It has, however, great interest for the surgeon, for its natural course is extremely fatal, while surgical interference has shown itself able to save more than one-half of these patients.

General acute peritonitis does, undoubtedly, occur, in which there is no effusion of liquid. Such instances, I believe, are very rare. Of this subject Dr. Truc says, "Purulent peritonitis is the usual form of acute inflammation of the peritoneal serous membrane," and he further quotes Besnier as saying that an acute inflammation of the peritoneum never produces a transparent serous fluid, and that this rule is without exception. That is, that the effusion, which almost always occurs, is to a greater or less extent purulent.

Therefore in this, as in the preceding classes of cases that we have passed in review, the surgeon has to deal with pus in the abdominal cavity. The results thus far obtained by abdominal section, as stated by Dr. B. F. Curtis, are eight recoveries (to which may be added one by Dr. Marcy, of Cambridge, and one by Buchanan, of Glasgow) and three deaths. In the latter, the operation was performed too late to be of any avail.

Tubercular peritonitis is so widely separated by its cause and course of development from the other forms of peritoneal inflammation that we have considered, as to render it a very distinct affection. Yet as the surgical treatment of it, entered upon sometimes through a mistaken diagnosis, has given some brilliant results, it seems important to refer briefly to a few of these cases and note the existing conditions in which laparotomy has been able to effect a cure or great amelioration. At first thought, recalling the pathology of this affection, it would seem impossible that any surgical interference could be other than disastrous. Still, when we remember that many tuberculous joints have been cured by free incision and drainage, this treatment as applied to the abdominal cavity becomes more reasonable.

[5] Lancet, Feb. 20, 1886.
[6] Reported by Buckmaster, Journal Medical Sciences, April, 1887.
[7] Glasgow Medical Journal, 1886.

Spencer Wells[8] reports two cases. In both there was a large amount of liquid. In the first it was serous, in the second of greater consistency but not pus. The peritoneum was covered with tubercular granulations. Both patients recovered, and continued in good health after the operation. Lanois reports a case in which he made an abdominal section. The effusion was purulent. Patient recovered.

Dr. Wylie, of New York, reports two cases cured by laparotomy and drainage. Before this Society in 1885, Dr. Homans gave the history of one in which he made an exploratory incision that was followed by an excellent recovery. Several other successful cases have been recorded.

In all of them there was quite a large effusion of liquid, sometimes serous, oftener sero-purulent. Thus the tubercular form has had one condition in common with the other peritonites, namely, liquid in the peritoneal cavity, and this often containing pus elements.

The patients that recovered were in fair general health, and the only local manifestation of the tuberculous diathesis was in connection with the peritoneum.

An article treating of the various classes of pus-forming peritonites and omitting all consideration of the puerperal, the most septic and purulent of all, would be a very incomplete one. But I have already so trespassed upon your time, that I must be content with a brief reference to a single form of puerperal peritonitis. I refer to that which follows abortions, either accidental or induced, but which exceptionally is seen after labor at full term. Showing itself at a later period after the parturient act, than is the rule with more acute peritonites, it commences with abdominal pain, increased temperature and pulse-rate, all in moderate degree. Tympanites more or less marked is always present. All these symptoms become progressively more severe. Vomiting and diarrhœa supervene, the features gradually acquire a pinched and anxious look, the pulse becomes thready and very rapid, the extremities cold, and the patient dies a few days after the commencement of the attack.

I have made three autopsies in cases of death from peritonitis after abortions. In all of them the post-mortem appearances have been very uniform. I have found from five to ten ounces of thick purulent liquid free in the peritoneal cavity, the intestinal folds bathed with pus and agglutinated more or less by fibrinous adhesions, and the general peritoneum deeply congested, especially in the vicinity of the pelvis. Dr. Draper, Medical Examiner at Boston, in reply to a letter describing the conditions mentioned above, and asking the result of his larger experience in these cases, writes as follows: "My observations correspond closely with your own, in the pathological conditions usually resulting from criminal abortion.

"In nearly all the cases in which death resulted from secondary complications, and not during or immediately after the operative interference, I have found the cause of death to be peritonitis, with the post-mortem appearances which you describe. Usually, I have traced the course of events in *this way:* a sloughing placental site, endometritis, salpingitis by continuity; finally, peritonitis. My cases number twenty-seven, of which more than half have peritonitis written after them."

Upon this subject, Dr. Harris, Medical Examiner, says: "An examination of my records of autopsies for the past ten years shows that generally, after death by abortion, I have found extensive peritonitis, the intestines glued together, and to the peritoneum. The abdominal cavity has contained a large quantity of offensive pus. The pus was largest in amount in those parts of the abdomen to which it would naturally gravitate. There has also been, generally, metritis and salpingitis, on one or both sides. In cases where death has occurred early, the appearances mentioned above have been much modified, or altogether absent."

Against this form of purulent peritonitis, medical treatment has no resources. It is in every instance necessarily fatal. I know of no case in which surgical interference has been attempted in the treatment of peritonitis following abortion. Yet, since abdominal section, with irrigation and drainage of the peritoneal cavity, as we have seen, has combatted successfully other forms of peritonitis, septic and purulent, like this, I think we may reasonably hope that laparotomy may, in the future, save, at least, a portion of these unfortunate patients.

Mr. Tait, who can speak upon the surgical treatment of peritonitis in general with the authority of an experience greater than that of any one else, says, in a written communication to Dr. Truc:

"In the presence of a grave peritonitis, I occupy myself but little with its cause and character. I first freely open the abdominal cavity, and then conduct myself according to the indications furnished by direct inspection."

Finally, an investigation of the causes that give rise to purulent effusions within the peritoneum, and a consideration of the results obtained by surgeons up to this time by laparotomy, tend to the conclusion that, whenever pus exists in the cavity of the peritoneum, our only resources are in abdominal section, irrigations, and drainage.

The further lesson unmistakably taught is that this simple operation will have a more extended field of usefulness than almost any other that has been an outgrowth of the parent operation, ovariotomy.

[8] Tumors of the ovaries and uterus. Wells.

CARLSBAD.[1]

BY HORATIO N. BIGELOW, M.D.

Chronic Conditions of the Stomach:

Catarrh. "Some medical men think that the mineral waters of Carlsbad are indicated neither for patients either in the tonic or atonic form of catarrhus ventriculi. I cannot, however, share this opinion; from my personal experience, on the contrary, I am happy to state that I have obtained remarkable results in these cases (of course not accompanied by organic derangement), by a treatment quite in opposition to that usually applied in cases of catarrhal affections of the stomach; by substituting a different diet, and principally by directing them to use the waters in a different way. These must be taken in a cooler state, and only in minimal quantities of from three to six ounces, twice daily. Should constipation set in, Carlsbad salts and all other purgatives are to be avoided, and only cold injections to be used. The catarrhal affections of the stomach frequently extend into the duodenum (catarrhus gastroduodenalis), and further into the larger, and in long-standing cases also the smaller biliary ducts, so that stagnation of the bile

[1] Concluded from page 124.

and jaundice supervene. It is evident that Carlsbad is especially indicated in such cases, and the use of its waters attended with the greatest success." (Kraus.) I have been much struck with the readiness with which Dr. Grünberger meets each symptom in these troublesome cases. How very carefully he regulates the diet, changing it, in some seemingly insignificant detail, to meet a fresh emergency. How well he handles the epigastric pain, and how scientifically he found means to remedy the constipation, which depends upon so many different causes. Of course, all this can only come of an exceedingly large experience. When a physician sees daily during the season from forty to seventy-five cases, all with faulty digestion or used-up livers, it is not to be wondered at that he should reach a precision in diagnosis and a tact in therapeutics which the ordinary general practitioner can never reach.

Uric Acid Diathesis. "In gout, the so-called uric diathesis with or without dependent catarrh of the pelves of the kidneys, bladder, and urethra, renal calculi, and the like, it is a matter of common experience that all alkaline waters, including those of Carlsbad, are beneficial by lessening the irritation caused by the acid, but chiefly, according to Leichtenstern, by their washing out that which stagnates in the tissues and joints, their oxidation of uric acid into urea in the body having no proof." (Page.)

The experience of the leading physicians here is to the effect that *all* forms of *gout* will yield to the use of Carlsbad waters directed by intelligence. While they have no influence whatever upon chronic indurations, the deposits capable of absorption will generally disappear. Also in gravel, the waters are strong enough to dissolve these formations in the tubes, and to eliminate them entirely by increasing the flow of urine. And what I have written in the foregoing conditions will apply equally well to dyspepsia, chronic constipation, intestinal catarrh, catarrh of the bladder, anæmia and diarrhœa (irritative and eliminative). "Another form of dyspepsia occurs in pale, anæmic persons, as in young women who suffer from chlorosis. There are tenderness and pain in the epigastrium, aversion to food, weariness of the whole muscular system, and palpitations occur on making the least effort. My friend, Dr. Grünberger, of Carlsbad, gives a lively description of the contrasted sufferers who seek relief at the springs. 'To the pale miss, who answers to the above description, her companion at Carlsbad offers a striking contrast. He is well nourished; his rubicund face declares that he knows the delights of dining, and that he takes frequent pleasure in champagne, sherry and brandy. When you remark his absence for two or three days at a time from the morning promenade around the springs, you may be sure that the gout, in addition to dyspepsia, has him in keeping; he suffers acutely from effusion into one or more of the principal joints, and plenty of uric acid is to be found in the deranged secretions. In spite of the waters, all seems to be going wrong. But after a cure continued through a few weeks, the sharp contrast between the two invalids is wonderfully lessened. The pale miss is invigorated, her appetite increases, she has gained in weight; while the gouty effusion of her companion is gone, his step is firm and sure again, the dyspeptic symptoms are relieved and the action of the digestive system has again become normal.'" (Harper's, 1883).

Matters of Interest to Gynæcologists. Pale, anæmic women, who won't get fat, despite our utmost endeavor, who never menstruate sufficiently, or painlessly, whose sleep is never wholesome, and whose aches and pains are legion and cannot be located, almost always do well in Carlsbad. Now I attribute this to many reasons. If the lining membrane of the uterus be adenoid in nature and structure, as recently demonstrated (Johnstone, British Gynæcol. Society), it will be subject to the same irregularities and deficiencies of blood-supply that control similar tissues. Again, there seems to be more than a casual relationship between portal circulation and menstruation. I have not infrequently noticed that many women would menstruate much better when the liver functioned normally. Most of these anæmic women are victims of constipation — a mean, nasty stoppage that baffles the physician's art. The Carlsbad water overcomes the torpidity of the intestine, it stimulates the liver, and it supplies the blood with something that was wanting; that is, it enriches the arterial supply. When the whole system begins to participate in the change, the uterus *must* follow suit. Menstruation approaches normal, the appetite is strengthened, sleep improved, constipation dissipated, and the whole constitutional tone is improved.

Chronic Metritis, with dislocated Uterus fixed by old Adhesions. It is quite common to find women here for treatment for enlarged livers who have also conditions such as this. It is fortunate that the Moor baths can be taken here just as well as at Franzensbad, and that their use does not at all interfere with the use of the waters. From close observation of many cases, I know of nothing half so potent for good as these Moor baths in women who have had attacks of para or perimetritis, or who have chronically enlarged uteri. The cases that came twice a week to the clinic of the Gynæcologist, that patiently pay their fees and never get better, the pale faces that haunt our slumbers, murmuring ever the sad complaint "You take our money but you do us no good," are just the ones that will bless the physician who sent them to Carlsbad. Indeed, *I* don't know of anything else that will alleviate the suffering of these women. It is well to remember when sending patients here for troubles other than pelvic, that the special disorders can also be treated here, coincidently with the liver, should such co-exist.

Of Interest to Dermatologists. As I know little or nothing of skin diseases, and as I have seen very few "cutaneous" patients here, I must take the dictum of Dr. Kraus, who says: "Diseases of the skin only have to be considered so far as they are connected with stagnation of the blood or with disorders of the abdominal organs, and there is no doubt that the regulation of the circulation, and the amelioration of the debilitated constitution will have a beneficial influence on the healing of some diseases of the skin, constituting, in fact, the necessary conditions for their entire cure."

The use of the Carlsbad waters may be recommended especially in cases of:

(*a*) Erysipelas migrans, principally if the patients show a constitutional tendency to this affection.

(*b*) Sclerosis of the skin, showing itself on the calves of the legs, in consequence of repeated attacks of erysipelas.

(*c*) Urticaria.

(*d*) Pemphigus, especially in its milder forms.

(*e*) Eczema, likewise in its milder forms.

(*f*) Morbid tendency to furuncles, so frequently met with, unconnected with diabetes mellitues.

IV. CONTRA INDICATIONS.

Kafka writes as follows:

(1) All the febrile phlogistic diseases and the acute exanthemas.

(2) An excessive irritability of the vascular system, if the menstruation and the hæmorrhoidal flux are too copious.

(3) Tuberculosis and pulmonary phthisis, all considerable suppuration of external or internal organs; ulcerated carcinoma of all organs, syphilitic ulcers.

(4) Weakness from old age and all morbid conditions, with feebleness of the vital power and anæmia.

(5) The following organic lesions: aneurism, atheroma of the great vessels of the heart and anchylosis.

(6) Pregnancy in very feeble women, who are very thin, anæmic, and with a disposition to miscarriage and to hæmorrhages.

I would add to this list —

(7) Bright's disease of the kidneys.

(8) Diseases of the brain and spinal cord.

(9) Malignant degenerations, (as the waters often hasten death).

V. THE MODUS OPERANDI OF THE CURE.

Kraus sums up as follows:

A. *By coming into immediate contact with the mucous membrane of the stomach and the intestinal tract, the waters act* —

(*a*) As soothing, invigorating, and regenerating agents on the nerves of the stomach, whence the increased appetite and the pleasant, warm sensation propagating itself from the stomach over the whole surface of the body.

(*b*) In a healing way in cases of simple erosions and ulcers of the mucous membrane of the stomach and duodenum.

(*c*) As correctives of the too abundant secretion of acids in the intestinal tract.

(*d*) As gentle purgatives and accelerators of the peristaltic action, removing the viscid mucous secretion, and mechanically dissolving the hard, dried-up fæces; as a general result of these influences, the mucous membrane of the intestinal channel is energetically stimulated to increased secretion.

B. *Being absorbed by the blood, the waters act* —

(*a*) By dissolving the concentrated and obstructed bile in the biliary ducts.

(*b*) By changing the condition of the blood, which, in its venous state, principally stagnates in the mesenteric vein and its branches; thus the waters regulate and increase the venous, and consequently, also the arterial circulation.

(*c*) By relieving the lymphatic glands and vessels of the thick and concentrated lymph contained in them.

(*d*) By removing the fat accumulated in the subcutaneous areolar tissue and other organs, and by causing old inflammatory residues (for instance, in the peritoneal cavity) to be absorbed.

Fundamental principles to be taken into consideration when prescribing the waters for internal use:

(1) The cooler springs are only slowly absorbed by the system, while the hotter waters are taken up more rapidly.

(2) Patients whose action of the heart has to be watched with care, and whose vital energy will not submit to much stimulation, must partake of the cooler springs.

(3) For acting more energetically, the hotter springs are made use of, if the constitution of the patient will permit. The particular spring selected is not to be changed without sufficient reason.

(4) The waters, as a rule, are taken in the morning, before breakfast, as the empty stomach will require less time to absorb the waters.

(5) The quantity for daily use is not to exceed six tumblersful (thirty ounces), and it is advisable to begin with two or three tumblersful, and in many cases, even with less. After several days, the quantity may be increased, this depending partly on the individual constitution of the patient and on the respective disease, partly on the effect already attained, or still wished for.

(6) The tumblerful of the water is to be consumed slowly (in from one to three minutes), a pause of twenty minutes or more being made between each tumbler, according to the state of the patient's digestion, and moderate walking should be resorted to during this time.

(7) After finishing the last tumblerful, the patients ought to walk about until they feel hungry for breakfast, which generally will be the case in about one hour's time.

VI. THE HYGIENE AND DIETETIC REGULATIONS.

"In general, starchy food, sweets, butter, fats and gravies, salads, pickles, condiments, and the like, are prohibited; also alcoholic beverages, particularly champagne and Rhine wines, although a moderate amount, at dinner, of claret, or a glass or two of Madeira or sherry, may be allowed to the aged or infirm, or those in the habit of drinking; ice-water is also forbidden, and in place of it, is used the Gieshübler, an excellent table-water, that comes from the Gieshübler simple acidulous spring in the neighborhood. Bread is thoroughly roasted in slices, called rusks or swiebacks, besides which, at dinner, is allowed in most cases a moderate amount of untoasted bread, made up with or without butter (Kaiserbrod, Wasserbrod). Fish, except salmon, which is thought to contain too much oil, and such meats as roast beef or mutton, beef-steak, mutton-chops, and poultry without dressing, are allowed in moderate quantities; also, green vegetables, such as string-beans, spinach, cauliflower, and cabbage. Included in the cure is exercise of some sort, chiefly walking. For this purpose, a variety of delightful walks have been constructed, and are kept in thorough repair. In this respect, and in the thorough system used regarding all the factors of the cure, managers of many of our American watering-places would do well to take lessons from their Bohemian friends across the water." The Gieshübler Sauerbrunn is a great institution. It is one of the best of table-waters, and is valuable in some forms of dyspepsia, in the uric-acid diathesis, gravel, stone in the kidneys, gout, and diabetes (see Garrod). Now, as the water is not to be highly recommended in Carlsbad, and as most patients are allowed no beer and little wine, Gieshübler becomes a boon beyond all estimate. Between two and three million bottles are exported each year to England and France. The bread and coffee in Carlsbad are beyond all praise. Nowhere in the world does one find better. The beer is highly spoken of, but fat men longing to get thin are

also told to avoid beer as religiously as ascetics do the Devil. Coffee is permitted in moderation, but most physicians here would much prefer that their patients should shun it altogether. Milk is taken hot by those with sensitive stomachs. In aggravated dyspepsia, nothing is permitted at first but hot milk; later, a thin chicken-soup; then chicken-hash, made of the white meat, and the yolks of two raw eggs; then a little raw Westphalia ham, chopped up fine, and so by gradual steps, to a full, but simple meal. The daily life, so far as it is possible to do so, is spent out-of-doors. Even if one be very weak, and cannot walk much, he should sit for hours in the sun, listening to the music, and watching the crowds of people moving by. Warm clothing is always needed, and one cannot be too careful about exposure, as the system becomes superlatively sensitive after taking the mineral waters, and that reminds me to say, just here, that no one should even come to Carlsbad without a variety of changes. Winter clothes, autumn and spring clothing will always be necessary. Of summer clothing, I cannot write advisedly. It is now almost June 1st, and there seems to be no prospect of any immediate necessity for anything thinner than winter-flannels; indeed, some gentlemen still appear in fur overcoats.

VII. THE BATHS.

(*a*) Common or sweet water baths. (*b*) Mineral baths. (*c*) Moss baths. (*d*) Vapor baths. (*e*) Douche baths. (*f*) Steel baths. (*g*) Sauerbrunn baths.

The entire medical experience of Carlsbad for hundreds of years bears witness to the beneficial influence of baths in certain diseases. The medical man who wrote an article in *Harper's* upon Carlsbad says: "The peat-baths, or mud-baths, have gained much in popularity within a few years, and a large building has been erected since 1880, devoted exclusively to this singular form of the cure. The material employed for the mud-bath is a rich black peat; it comes by rail from the neighboring watering-place of Frunzensbad, some two hours distant, where Carlsbad owns a tract of moorland, which supplies the peat. It is rich in mineral constituents, and it makes what may be called a clean mud. First pulverized, but not too finely, then screened and freed from accidental impurities, it is mixed with the hot Sprudel water when the bath is ordered, and rolled in a stout wooden tub to the bath-room, where it stands, fuming, by the side of a similar tub filled with warm, soft water. One's first mud-bath is an odd experience. I confess having felt a slight reluctance to immerse myself in this malebolgian mass of peat-mud, although it fumed not unfragrantly, and its temperature, 102° F., was delightful. It seemed like undoing the results of a lifetime's ablutions. The difficulty is to get your first foot into it; that done, there is no more hesitation; you sink luxuriously into the warm, fuming mass. Mortal body was never received into a more deliciously soft embrace than that of this semi-fluid peat. Its viscous resistance to my movements, its weight and warmth, the clinging titillation of the unresolved lumps of mould, its faint and fragrant earthy odor, all combined to make a strange experience, even for one who has tried many baths in many places. It was no less delightful than strange. Whether for the invalid or the well man, the peat mud-baths at 31° Réaumur are one of the most luxurious enjoyments. I took them as a pleasurable incident of a visit made for the purposes of specific study; but if I should ever contract to furnish an earthly or a Mohammedan paradise, I should fit up an entire basement-story of the paradise with mud-baths." I purposely avoid all discussion about the way in which these baths accomplish the ends claimed for them by clinicians, because but very little is known *absolutely* upon the subject. Dr. Page, in his article in the *New York Medical Record*, enters somewhat elaborately into the matter, but arrives at no precise conclusion. In some diseases of women, the moor-baths *do* reach results beyond the grasp of any other treatment. They do this, in my very modest opinion, by pressure, by heat, and by irritation.

VIII. THE CITY OF CARLSBAD.

Carlsbad is —

11	hours from Berlin.	8	hours from Leipzig.
21	hours from Bremen.	30	hours from Lemberg.
16	hours from Breslau.	14	hours from Magdeburg.
20	hours from Budapest.	8	hours from München.
7½	hours from Dresden.	30	hours from Paris.
13	hours from Frankfort on M.	17½	hours from Stettin.
14	hours from Frankfort on O.	13	hours from Stuttgart.
21	hours from Hamburg.	18½	hours from Strassburg.
17	hours from Hannover.	30	hours from Warschau.
19	hours from Cassel.	13	hours from Vienna.
20	hours from Köln.	39	hours from Triest.
24	hours from Königsberg in Pr.		

It has 12,000 inhabitants with an average of over 28,000 visitors during the season. The average temperature for the year is 7.39° C., average barometric pressure 728 millimetre. The mean temperatures are summer, 66.5°F.; spring and autumn, each 47°; winter 33.5°.; The town itself has an elevation of 1,214 feet above the Adriatic Sea; in latitude, 50° north, longitude 13° east (from Greenwich). Like almost all Austrian villages, Carlsbad is gemüthlieh, and one does not seem to weary of the dolce far niente life. It nestles very prettily in the lap of many hills, whose beautiful foliage is brilliant in every shade of green, while the little river Tepl rolls along at the base of the woods, dividing the town into two parts. Under the generous management of the Mayor and his assistants the streets are kept in most perfect order, and I know of no summer resort anywhere where the walks are so trim and tidy, and where so much is done to secure the comfort of visitors. The shops are brilliant and attractive, not only with the laces, the gloves, the beautiful glass, and fascinating porcelain for which Carlsbad is celebrated, but various quarters of the world contribute specimens of their industries, so that we can buy here, as well as in any large mercantile city. For the moderate pedestrian Carlsbad offers inducements. There are many walks of from four to fifteen miles which are unsurpassed in natural beauties, and there are short ones of equal beauty for invalids. There is music, and good music at that, somewhere, three or four times a day, military music three times a week, and a symphony concert that would not disgrace a Thomas orchestra once a week. Hungarian music, gypsy music, and a theatre, which is a perfect gem, one of the very prettiest in the whole of Europe, "was willst du noch mehr."

IX. COST.

There are in Carlsbad about nine hundred or one thousand houses all of which are pensions, or houses in which rooms are rented. Indeed, one wonders where the actual all the year round inhabitants of Carlsbad live, as there seem to be no private houses. If no previous arrangements have been made, it is

better upon arrival in Carlsbad, to take the omnibus (forty vereuzers) which will take the visitor and his luggage directly to the omnibus office in the immediate centre of the town. Then leaving luggage here, one can leisurely saunter about and suit himself as to quarters. My own individual preference is for the Schlossberg, because by reason of its elevation, the air must be always pure and sweet. The approach is only a slight ascent, and it is very convenient to most of the springs. At the summit is Pension König-Ulla, beautifully situated, and the Mecca of English people. Then come the Westminster, Victoria, Kaiser Haus, Herzog v. Edinburg, Englisches Haus, all of which are first-class. This section of the town is much frequented by Americans and Englishmen. During the season, rooms (bedroom and sittingroom) range in price from twenty-five to thirty-five guldens per week, according to situation. Single rooms from fifteen guldens per week. The Park Strasse and Garenzeile are full of inviting houses, many of which are deservedly popular, and the situation is excellent. Those who prefer to live in the town itself will find all along the Alte and Neue Wiese rooms to rent, and the rooms in Carlsbad are beautifully neat and most of them extremely attractive. Of hotels there are Anger's, Donau, Erzherzog Carl, Drei Fasanen, Stadt Hannover, Loib, Morgenstern, National, Pupp's Etablissement, Goldener, Schild, etc. The Hannover is on the Schlossberg, nearly opposite the Schlossbrunn. Pupp's is a very elegant affair (always full), at the end of the Alte Wiese, Anger's is on the Neue Wiese next to the Opera House. The National is on the Garenzeile Strasse, and has the appearance of being very homelike and comfortable. The price at most of these hotels is about the same, and is not higher than at equally good inns at other summer resorts. The Goldener Schild is very popular and has this year been enlarged and beautified. On the Garenzeile the following houses are first rate, with fine views. Mirabel, Beethoven, Humboldt, Concordia, Union, Villa Herschl. and Guttenberg. On the Park strasse Villa Schnee, Kaiser Josef, Rubens, Schubert, Villa Schwalb, Goethe, Uhland, Lessing, Venedig, and Kaiser Franz. The Milton and Shakespeare are beautifully situated on high ground, with unobstructed views, and to those who enjoy a walk of ten or fifteen minutes, these houses offer great advantages. On the Alte Wiese, Drei Schwalben, Königin v. England, Grünes Schiff, Goldener Anker, Erzh. v. Œsteweich, Pelikan, Blauer Hecht, Weisse Taube, Goldener Fasan, Elefant, Zwei Storck, Mozart, Meufräulein, etc. The rocks in and about Carlsbad bear the written testimony of gratitude of many patients; I wish to add my voice to that of the many, and as Goethe said:

> Was ich dort gelebt, genossen,
> Was mir all' dorther entsprossen
> Welche Freude, welche Kenntniss
> Wär'ein allzulang Geständniss!
> Mög' es Jeden so erfreuen,
> Die Erfahrenen, die neuen!

— A correspondent writes to the *Pacific Medical and Surgical Journal* of a patient with "incarcerated" inguinal hernia, who, taxis having failed, was taken to an hospital for operation, riding nine or ten miles on a spring mattress on a spring wagon. The jolting which he had received on the passage had reduced the hernia when he reached the hospital.

NOTES OF PROGRESS IN PHYSIOLOGY.[1]

BY JOSEPH W. WARREN, M.D.,
Instructor in Physiology in the Harvard Medical School.

RECENT OBSERVATIONS ON THE HEART.

The profession has long been familiar with experiments on the isolated heart of the frog, and such work has led to very important results. I infer from the slowness with which the information manifests itself in medical literature that many do not yet know that a very ingenious method has been worked out for doing similar work with the mammalian heart. We owe this addition to our experimental resources to Prof. Martin[2] of Johns Hopkins University, although he modestly shares it with various pupils, and calls it the "Baltimore method." The excised frog's heart beats vigorously for a considerable time, with very little attention, and adapts itself quite easily to a change of diet, so that it has been comparatively simple to keep it going long after the body to which it belonged has begun to break up in postmortal putrefaction. The mammalian heart, on the other hand, had usually been considered a particularly intractable organ. When removed from the body it would beat after a fashion for a few minutes and then die. No convenient plan had been devised for continuing its activity so as to permit much study of its behavior apart from the complex nervous and metabolic relations which belonged to it while in the living body. Martin came to the conclusion that the method of nourishment was the main cause of the difficulty in manipulating the mammalian heart. The frog's heart has thin walls and takes what it requires from the fluid in which it is bathed; the mammalian heart, on the other hand, is fed through the coronary arteries and derives little or no direct benefit from the fluid in the cavities or about the outside. The problem thus appeared to be to keep up a circulation through the heart and also through its own vessels after excluding the rest of the animal. His method, then, without going too much into details, consisted in shutting off the blood-supply to the rest of the body and sending defibrinated blood through the heart and lungs. This can be done by ligaturing the aorta beyond the arch (using its earlier branches in the thorax for outflow and pressure tubes) and by ligaturing the vena cava inferior and using the vena cava superior for the blood flowing in from a reservoir. The lungs are retained as the most convenient means of aërating the blood, and they are inflated by a respiration apparatus. It would doubtless be practicable to remove these too, and to arterialize the blood by some other method; Martin proposed to use this modification, should it become desirable, but, so far as I have noticed, this plan has not been carried out. Starting then with a narcotized and artificially respiring animal, the influence of the central nervous system must be rapidly destroyed when the bloodvessels going to the head are tied. If now the *venæ cavæ* and the aorta are also tied at suitable points, and a flow of defibrinated blood is set up into the right auricle we have the most favorable conditions for continuing the life of the heart while all the rest of the animal dies. It has proved that under such conditions the heart (dog or cat) will continue to beat for some hours. The organs required (heart and lungs) are retained in the opened thorax simply be-

[1] Concluded from page 131.

[2] Martin. A new method of studying the mammalian heart. Studies from the Biological Laboratory of the Johns Hopkins University, Vol. ii p. 119.

cause this is the very best box which can possibly be devised for the purpose, and the body and the blood food are placed in a large glass case where a suitable temperature can be maintained. Such is a brief outline of the method.

For experiments of this character dogs were found to be most suitable. As a nutrient liquid, the blood of these animals would be best, but Martin found that he got very good results with such blood when diluted with an equal volume of a five-tenths per cent. solution of sodium chloride in distilled water (or with one-third its bulk of a seven-tenths per cent. solution) or even with defibrinated strained calf's blood. Calf's blood proved, however, to be less satisfactory than dog's blood on account of its more readily causing pulmonary œdema and a considerable effusion in the pericardiac sac.

The advantages of this way of working are quite evident. We have to do with the heart itself, for all the numerous extrinsic influences coming from the central nervous system with its complex reflex stimulations as well as the influence of the products of the metabolic changes going on in other organs are excluded. It is exceedingly improbable that the lungs under such conditions can have any direct influence on the action of the heart, and should their presence appear to be in any way detrimental, it will probably be easy to exclude them also.

By means of this method several interesting points have been cleared up. Martin himself examined the influence of blood-pressure on the rate of the heart beat.[6] Previous observers had obtained discordant results even when the extrinsic nerves of the heart had been divided in the living animal. As Martin points out, this might be due to a variety of causes besides the mere raising of the pressure brought about by clamping arteries. It would probably alter the blood flow very materially, and change the pressure of the venous blood entering the heart; and the proceeding would doubtless also affect the temperature of the blood and more or less vary the quality of it chemically. With the isolated heart, on the other hand, it is possible to keep the conditions of temperature and venous pressure comparatively constant during considerable variations of arterial pressure. The quality of the blood flowing only through the heart and lungs will not probably be easily or rapidly changed, and it is always a simple matter to substitute fresh blood whenever necessary.

It was found that so long as the inflow into the right auricle took place at a pressure not greater than that due to a column of blood ten centimetres in height, most considerable changes in the arterial pressure produced by clamping the outflow tubes and measured in the carotid artery, caused no marked change in the rate of the heart beat. This was found to be true for arterial pressures varying from 25 to 160 mm. of mercury for the hearts of small dogs. When, however, the arterial pressure was lowered to less than 20 mm. of mercury an indirect effect seemed to be produced. The heart beats were unaltered in frequency for a minute or two, but then became sometimes slower, probably from a deficient nutrition on account of the low pressure in the coronary arteries. Later experiments made by Howell and Ely showed that for some dogs the danger line lies rather higher, and that when the arterial pressure is lowered to 30 mm. of mercury, the influence of mal-nutrition becomes apparent.

It was also found that the pressure at which venous blood enters the right auricle might be considerable, (due to a column of blood 40 centimetres in height, or even as high as 70 centimetres, according to later experiments) and yet no change in the rate of the heart occur unless combined with an exceedingly high arterial tension. Such a combination is obviously pathological, and probably never occurs normally. The investigation of this point has not, I believe, been fully carried out.

The observers just mentioned[7] carefully examined the influence of arterial pressure on the duration of the systole and diastole, since it is conceivable that although the heart's rate of beating does not vary there may be an alteration in the parts of which a single beat is composed. It was found, however, that changes in arterial pressure between 50 and 160 mm., of mercury had no direct influence whatever upon the duration of the systole or the diastole of the heart-beat in the dog.

In order to test the applicability of the method of pharmacological investigations, experiments were made with blood, to which a small quantity of pure alcohol had been added.[8] The general statement of their result is this:

> "When defibrinated blood containing one-half of one per cent. by volume of ethyl alcohol is supplied to an isolated dog's heart which has been hitherto working with uniformity, the invariable result is a very rapid and marked diminution in the work done (indicated by the quantity of the blood pumped out from the left ventricle) by the heart in a given time. When the blood contains only one-fourth of one per cent. of alcohol, the result is, in most cases, the same, but sometimes is little or none. After the action of the alcohol has been fully manifested, the heart can, in many cases, be restored to its original working state if supplied with defibrinated blood containing no alcohol. Blood containing but one-eighth of one per cent. of alcohol exerts no influence upon the work done by the heart, at least, for several minutes."

It was observed that the change in the work was associated with a marked swelling of the heart in the pericardial sac, although a minute opening had been made to permit the free escape of the lymph, which is apt to collect in these experiments (probably on account of some hindrance to its flowing off). The explanation of this condition is to be sought in a change of the systolic contractions, or, in the words of the paper:

> "The action of alcohol administered in the manner and doses above described is, without primarily altering the force of the heart-beat, to alter its character, so that the ventricular cavity is not obliterated at the end of systole (as in the normal heart-beat), and less so the longer the alcohol has been administered. At first, this incomplete systole is compensated for by a more extensive diastole, so that the difference between the capacity of the ventricle in complete diastole and that in complete systole remains the same as when the organ was normally beating. Consequently, the quantity of blood pumped out at each beat remains as great as before. If the heart be confined in the pericardium, it soon, however, ceases to have room to swell during diastole to a size sufficient to compensate for its incomplete systole; and thenceforth, as the swelling increases, the difference between diastolic and systolic capacity becomes less and less. As the necessary result, the quantity of blood pumped round by the organ is proportionally diminished. Removal of the pericardium prevents this result, at least, for a considerable time."

To what extent the increase would continue after

the removal of the pericardium, was not determined in these experiments. It is probable that the effect above detailed is due to a direct action on the muscles of the heart, as has been shown for the action of various alcohols on the heart of the frog. This investigation also suggests that alcohol may do harm in cases where there is a pericardial effusion, and the room for the heart's expansion is limited. On the other hand, it should be remembered, as I have elsewhere pointed out, that Martin, in another account of these experiments, has stated that the amount of alcohol which produces the results above given completely fails to do anything of the kind when introduced into the body by the stomach. Even when introduced by the vein, the effect is inconsiderable or transient. It is evident, then, that the alcohol is absorbed too slowly, and more or less completely transformed elsewhere in other organs or that some other nervous action is produced, which corrects the bad effect on the heart-muscles. Were this not the case, the damage done by alcohol, as it manifests itself in the heart action, ought to be a thousandfold greater and more frequent than it obviously is.

Among the most interesting experiments of this series, seem to me to be those of Martin, showing the influence of temperature upon the pulse-rate[9] of the mammalian heart. These demonstrated quite conclusively that the isolated heart is exceedingly sensitive to variations in temperature of the blood circulating through it. The temperature was varied between 28° and 40.5° C. (82.4°–104.9° F.), the pulse-rate rising or falling with it, as is shown in two curves appended to the paper. (The exact rate of the pulse is of no interest here, for, of course, the removal of the extrinsic inhibitory nerves alters the rate, as compared with that of the heart beating in full continuity with the rest of the body. But it does not appear from any of these experiments that this change in the rate affected the nourishment of the heart.) The temperature considered was the temperature of the blood as it came from the left ventricle; that is, the temperature of the blood which was sent into the coronary artery, and thus into the capillaries of the heart. This had been found to be of more importance than the temperature of the blood supplied to the right auricle, and which, of course, will undergo considerable cooling in the lungs before reaching the left heart and then the muscular tissue itself.

"It is not the temperature of the blood in its cavities which influences the rate of beat of the dog's heart, but the temperature of the blood sent to its capillaries. In other words, temperature changes do not influence the pulse-rate by stimulating the afferent nerves in the endocardium, which then act upon cardio-motor ganglia, but they act directly upon the muscle-fibres or nerve-cells of the organ."

When, then, the pulse becomes more rapid in fever, it is not necessary to assume any paralysis of a cardio-inhibitory nervous centre outside the heart, nor the effect of the products of an altered metabolism upon the heart itself, as an explanation. It may, however, be that such influences are also at work besides the changes of the temperature of the blood itself.

In another paper, the "Baltimore method" has been employed to study the work done by the heart.[10]

[9] H. N. Martin. The direct influence of gradual variations of temperature upon the rate of beat of dog's heart. Philos. Trans. Roy. Soc., Part II, 1883, p. 663.

[10] W. H. Howell and F. Donaldson, Jr. Experiments upon the heart of the dog, with reference to the maximum volume of blood sent out by the left ventricle in a single beat, and the influence of variations in venous pressure, arterial pressure, and pulse-rate upon the work done by the heart. Philos. Trans. of the Roy. Soc., Part I, 1884, 139.

The "work" is, of course, the quantity of blood pumped out, multiplied by the height to which it is raised; that is, the pressure against which the heart forces the blood. This may be conveniently calculated in gramme-meters. Measured in this way, it was found that "variations of arterial pressure from 58 to 147 millimeters of mercury have, practically, no effect whatever on the quantity of blood sent out from the ventricle at each systole," so that, one factor in the calculation being constant, it follows that "the work done by the left ventricle of the dog's heart varies directly as the arterial pressure against which it works within the limits named above."

The results obtained by varying the venous pressure make it evident that "the work done by the left ventricle at each systole increases with the venous pressure, but not proportionally, up to the point of maximum work." As Howell and Donaldson point out, the pressure in the right auricle in these experiments was much greater than the maximum pressure which other observers have met with there normally. This places "the right heart under conditions different from those which exist during life." When, however, the pressure in the left auricle was measured, it was found that the left side of the heart was working under conditions of pressure which could not be considered abnormal. After all, if we leave out of account the aspiratory action of the thorax, "it is certain that the most direct factor in influencing the quantity of blood sent out from the ventricle, and hence, the work done by the ventricle, is the intra-ventricular pressure, by which the ventricle is distended during diastole;" hence the authors consider that they were able "to confirm for the mammalian heart the statement made by Roy, for the frog's heart, namely: 'The work of the heart of the living animal is governed chiefly by the auricles, the ventricle influencing the amount of work done only indirectly.'"

Making use of the influence of the temperature to regulate the rate of beat, it was possible to study the relation of the latter to the work. In this way, the general fact was brought out that "a diminution of pulse-rate, brought about by lowering the temperature of the blood flowing into the heart, causes an increase in the quantity of blood thrown out from the ventricle at each systole, and consequently, an increase in the work done at each systole, and *vice versâ*." The changes of the outflow are not inversely proportional to the change of pulse-rate, and it is uncertain whether any more definite relation exists.

Another important point which Howell and Donaldson endeavored to examine is the amount of blood thrown out by the heart at each beat. Earlier observers had been obliged to use methods against which many objections may be urged. Some had studied the relation existing between the velocity of the blood-flow and the size of the vessels. In this way Volkmann and also Vierordt had calculated that each systole sends out from the left ventricle a quantity of blood equal to abqut $\frac{1}{180}$ of the body weight. In view of the chances of error the agreement in the results of these two observers may be considered almost accidental.

Fick, using perhaps, an equally untrustworthy method, but nevertheless applicable to man, had calculated the proportion as $\frac{1}{1000}$. In the experiments we are considering, it was found that "the mean ratio of the maximum weight of blood thrown out from the

left ventricle at a single systole to the whole body weight is 0.00117 or $\frac{1}{855}$ for a mean pulse-rate of 180 per minute." As the check of the vagus is removed in such hearts the rate is greater than normally. In the only experiment where the rate was nearly normal (120) the ratio of the blood sent out to the body weight, was about $\frac{1}{750}$. It is, of course, an open question how far this is applicable to man. The human heart has a slower heart-beat, and the experiments on the dog with varying the rate, showed an increased outflow for a lower rate.

It may be, however, that varying the temperature of the blood in some way affects the elasticity of the heart, and that the outflow thus obtained is not normal. On the other hand, it would be expected that the ventricle with each diastole would be distended to about its maximum capacity, and variations in the rate ought to have little effect on the amount sent out at each systole. Therefore, the authors conclude, we may not at present draw any very definite conclusions concerning the human heart with reference to the amount of blood sent out at each beat.

It is worth noting that in Martin's article on the effect of alcohol on the isolated heart, an experiment with a teetotaler is reported whose pulse was unaffected by 15 cm. of absolute alcohol in 50 cm. of water. Unfortunately only one experiment appears to have been tried.

Another method for heart work has been proposed by Dr. W. G. Thompson,[11] and has attracted some attention in the metropolis.

It consists in the employment of an ingenious arrangement for obtaining a successive series of instantaneous photographs whose study it is expected will yield valuable results. The apparatus appears, from the descriptions, to resemble one which Marey had already suggested. Although evidently useful for the demonstration of certain relations observable in the movement of the heart, neither the descriptions nor the pictures which I have seen, convince me that such methods are likely to be very profitable.

A new study of the cause of the first sound of the heart, or at least a fresh demonstration of the muscular element of it, has been recently made by Yeo and Barrett.[12] These investigators convinced themselves that when the blood-supply to the heart is shut off by compression of the veins, the first sound continues so long as the heart continues to beat. The method is considered by them an improvement on that of Ludwig and Dogiel (1868) where all the vessels are tied in succession and some blood may possibly be retained. The first sound also remained audible, and the same in quality, when the heart was removed from the body; and "a sound like the characteristic heart-tone" was still distinctly audible when the auricles and the auriculo-ventricular openings (valves) had been cut away, and only the apex of the heart remained beating on the finger-tip. In the words of the authors "a definite and characteristic tone similar in quality to the first sound, is produced by the heart-muscle under circumstances that render it impossible for any tension of the valves to contribute to its production."

[11] W. G. Thompson. Instantaneous photographs of the heart in motion and of peristalsis. New York Med. Rec. 1883, xxix, 360. A new apparatus for the study of cardiac drugs. Ibid. 1886, xxx, 261, 353.

[12] G. F. Yeo and J. W. Barrett. Note on the cause of the first sound of the heart. Journal of Physiology. vi, 145.

Thus the view of C. J. B. Williams, advanced over fifty years ago, receives a new confirmation, and the experiments of Ludwig and Dogiel are again supplemented, for almost precisely the same demonstration of the existence of the first sound, unchanged in quality, when the valves and chordæ tendineæ have been removed, was made by Arnold and Loomis in 1878.[13]

Tarchanoff[14] in a very interesting paper, has reported what seem to be genuine cases of willed acceleration of the heart-beat, although his article has attracted but little attention. Most of the cases of this character hitherto detailed, had not been altogether free from the suspicion that some other influence than mere will power was in play.

While examining the effect of beef extracts on the heart, Lehmann had his attention directed to the fact that the pulse-rate is often easily influenced by circumstances which have not ordinarily been supposed to be of much importance. In the study of this subject which he then made with Bleuler[15] the following general conclusions were reached, but obviously an independent confirmation of them is very desirable:—

(1) Drinking moderate amounts of hot water makes the pulse more rapid; while considerable quantities of cold water slow it. The increase is 3 to 8 beats while the decrease may be as much as 10. (Mantegazza has made a somewhat similar observation [Schmidt's Jahrbucher civ, 346,] and Winternitz in his Hydrotherapie evidently has this influence of cold water in mind.)

(2) Careful covering with heavy bed-clothes increases the pulse-rate along with the sensation of warmth; exposure of the naked body to a lower air-temperature lessens the rate markedly.

(3) Lehmann's pulse-rate was lowered by light reading lacking all excitement, but that of Bleuler was not perceptibly influenced.

(4) Every feeling of burning, pressure, or nausea, associated with the stomach makes the pulse more frequent; the same is true of feelings of fulness in the intestines, and especially in the rectum.

(5) Salts (Na_2SO_4; NaCl; $MgSO_4$), which have no specific action on the heart, influence the pulse reflexly according to the amount of the unpleasant sensations produced in the stomach and intestines. Here the influence of the rectum and of nausea is most marked. The effect of a meal as such, that is, cold food in moderate amounts, appeared to be negative, provided no special sensations in the intestinal tract were produced.

The older experiments of Kemmerich and of Bunge on the influence of beef-tea and extracts on the heart were at variance. The view of the former, that the action of these substances was like that of potassium salts, and, in fact, due to their presence, needed confirmation. Lehmann[16] has called attention to the fact that Kemmerich's experiments on himself show a rather more sensitive intestinal tract than is evident

[13] See J. W. S. Arnold. An experimental inquiry into the muscular element of the first sound of the heart. N. Y. Med. Journ., 1879, xxvii, 337.

in Bunge's investigations. Suspecting that these differences would explain some of the discrepancies of their results (as a reflex action on the pulse), he set to work to investigate this point. He found that:

(1) Ordinary *bouillon* [250 ccm. warm water, 2.5–5.0 extractum carnis, 4.0 Na Cl (or without)] had only the same effect as an equal amount of warm, dilute, salt solution, or warm milk, or even warm water.

(2) In a considerable series of experiments with larger doses (10, 30, 60 gm.) in lukewarm or cool water, the action on the pulse-rate was very slight, except as due to irritation of the intestinal tract, more especially of the stomach or of the rectum. When nausea or diarrhœa is produced, the reflex increase of the heart's action is evident. It passes away, however, with these other effects; for example, when the rectum is emptied. The action comes on more rapidly than it could if the *absorption* of the potassium salts were the important element, and does not last or increase, as it should if due to some special influence of these salts.

(3) Experiments with KCl [6.0–10.0] in warm or cold water verified this view, as well as the conclusions which Bleuler and Lehmann had drawn from the examination of other salts to which no particular effect on the heart is attributed.

(4) Long-continued doses of the meat extract or potassium salts given to white rats, as well as large doses given for many days to feeble or insufficiently-nourished, or fasting animals (rats and cats), also failed to demonstrate any deleterious action on health or weight. The amounts were varied up to one per cent. of the body-weight, and continued for thirty days. Lehmann also quotes an experience with two feeble children, who could take no milk, and, therefore, received large amounts of beef-tea (with or without eggs) for a long period, with great advantage.

The cutting up of the meat has an important influence on the character of the extract obtained. Thus Lehmann found that while solid beef gives up 69 per cent. of the entire ash, and 80 per cent. of the potassium salts, when heated with distilled water (80°–90° C.) for three hours, the same beef, cut up into dice, yields up 79 per cent. of its ash, and 98 per cent. of the potassium salts. The method of the Liebig extraction only takes out 60 and 66 per cent. of these, respectively, and this is due to the fact that the meat is boiled too short a time, or possibly, in too little water.

The usefulness of beaf tea (soups, etc.) lies then, according to Lehmann, (1) in their action as a substitute for a meal (with, perhaps, cerebral and muscular stimulation); (2) in stimulating digestion at the beginning of a large meal; (3) in making food more pleasant, acting as a spice.

ON THE TYPE OF RESPIRATION.

With a view to clearing up the vexed question concerning the costal type of respiration in women, Mays[17] has recently examined some Indian girls in the Lincoln Institution. Their ages ranged from ten to twenty years. He found that the full-blooded girls all had the abdominal type, while those of mixed blood showed the costal type with more or less distinctness. The variation in the type, then, is not due to sexual differences, as expressed in woman's monopoly of child-bearing, but would seem to be the outcome of the method of dressing adopted by the sex in civilized life. Mays thinks that the Indian's danger in the inevitable combat with consumption, which his contact with civilization has brought him, will lie in the incomplete thoracic expansion which abdominal breathing encourages. He also suggests that the constrictions practised by civilized white women may be of benefit to them by expanding their chests, and thus filling the apices of the lungs more completely. The thoughtful reader will see in this an inferential commendation of corsets and snug dressing, if not of tight-lacing. It will thus be possible for the energetic physician, when the triumphs of rectal insufflation shall have grown less brilliant, to introduce a new method of attacking, or, at least, of preventing consumption — a method which is sure to enhance his popularity with a large portion of the community.

Clinical Memorandum.

A CASE OF RÖTHELN OCCURRING DURING THE PUERPERIUM.

BY J. ALDAN KITE, M.D., NANTUCKET, MASS.

December 25, 1886, 11 P.M., saw Mrs. B., a primipar., aged seventeen, in the first stage of labor. Found os slightly dilated, pains transient. Gave one-eighth grain of sulphate of morphia subcutaneously. Delivered her December 26th, 11.15 P.M., of a male child, eight pounds; instrumental delivery. Forceps on head in first position after the occiput had passed the superior strait, as there was marked uterine inertia. Within one-half hour the placenta was expressed without force and found to be intact.

December 27th. Temperature 99° F., pulse normal. Lochia and urine satisfactory.

December 28th, 10 A.M. Temperature 100° F., pulse 90, compressible. Saw the patient at 4 P.M. Temperature 105.5° F., pulse 140; delirium; slight tenesmus over abdomen; suppression of lochia. 11.30 P.M., antipyrin had reduced temperature to 103.2° F. The pulse was 120. Vaginal injections of $HgCl_2$, 1–5000, at 115° F., had been used every two hours, also flax-seed poultices over abdomen. A rectal enema had effected a copious movement of bowels.

It is unnecessary to state my fears or record my intentions. I at last decided to wait before resorting to direct uterine applications or examination.

December 28th, 8 A.M. Temperature 101° F., pulse 96. Lochia still suppressed. An examination revealed the entire body curved with an eruption of rötheln, including face and even scalp.

The lochia made their appearance on December 30th, the tenismus remained until January 4, 1887. On January 2d, the temperature rose to 102.08° F., and then gradually fell until the normal was reached January 5th. The eruption had entirely disappeared by January 17th, and was followed by desquamation.

Mrs. B., had not left the house for three weeks prior to her accouchement, nor had there been a case of rötheln, to my knowledge, on the island for two weeks.

Aseptic precautions during and after delivery had been complied with.

Reports of Societies.

AMERICAN OPHTHALMOLOGICAL SOCIETY.[1]

TWENTY-THIRD ANNUAL MEETING.

THE EYE OF THE ADULT IMBECILE,

By CHARLES A. OLIVER, M.D., of Philadelphia.

Twenty young adult male imbeciles were examined, care being taken to exclude all but the proper class of subjects. Nineteen observations were obtained, from which were drawn the following conclusions:

First, The eye of the male imbecile adult is an organ which is capable of proper functional activity.

Second, By reason of early mental incapacity, the ordinary appearance seen in the used eyes of the mentally healthy are lessened in due proportion to the amount of work given to the organ.

Third, The eye of the imbecile, being practically an unused organ for close and careful near work, the distension of the globe and the elongation in its visual axis with consequent increase in index of refraction is almost entirely avoided, this being in direct ratio to use.

Fourth, The want of these physical changes may be considered as significant of a type of unused healthy adult human eyes.

Fifth, The healthy eye of the imbecile serves to teach us that the various conditions seen in the used eye of the mentally healthy must be considered as pathological changes, the representatives not only of general want of tone, but of constant and frequent abuse of a delicate organ.

Dr. Charles A. Oliver also exhibited water-color sketches of a case of double chorio retinitis with partial degeneration of the optic nerve, associated with curious lymph extravasation into the retina and vitreous, in a boy twelve years of age, who had had an attack of basilar meningitis five years previously, at which time eyesight became bad. No hereditary dyscrasis could be discovered. Vision was greatly reduced, and patellar tendon-reflex was almost abolished.

ADDITIONAL CASES OF HYPERMETROPHIC REFRACTION, PASSING WHILE UNDER OBSERVATION INTO MYOPIA,

by S. D. RIPLEY, M.D., of Philadelphia.

Thirteen carefully-studied cases in which the eye with hypermetrophic refraction had been observed to pass into myopia, had been recorded in the annals of the Society. To-day, the author brought forward nine additional cases, making a total of twenty-two. In all these cases, the state of the refraction had been repeatedly demonstrated under complete paralysis of the accommodation. In every case, there was well-marked retino-choroidal irritation, with asthenopia. Insufficiency of the internal rectus was noted in three cases, in all of which tenotomy of the external rectus was performed. In no case was emmetropic refraction observed at any stage of the progress. The condition seemed to pass from the shallow hypermetropic ball to the lengthened myopic eye by the turn-stile of astigmatism. A detailed record of the nine cases was given.

The most important measure in the treatment of these cases was considered to be the use of correcting glasses. When we consider the large number of cases which, at the first, present the same conditions as the cases reported, and which have subsequently had no return of the trouble, we cannot but think that the group of cases now presented are only those in which the treatment has failed, and that, without their correcting glasses, a much larger number would have pursued the same history. A study of these cases has demonstrated to the author the importance of astigmatism, when present in very low degree, as a factor in setting up those changes in the nutrition of the eyeball which result in impaired resistance to even normal intraocular tension.

[1] Continued from page 139.

THE PATHOGENESIS OF PTERYGIUM,

by SAMUEL THEOBALD, M.D., of Baltimore.

The generally accepted theory of Arlt that pterygium has its origin in a marginal corneal ulcer, to which a tag of conjunctiva has become attached, he thought was untenable, because, if this were its usual mode of origin, pterygium would be found approaching the cornea from every possible direction, since marginal corneal ulcers are not apparently more frequent in one position than in another. It is known, however, that such is not the case, but that pterygium is almost always situated directly over the recti muscles, and that, in a very large proportion of cases, it is over the rectus internus. The more recently proposed theory of Poncet, that pterygium is due to the presence of microbia, which tunnel their way under the corneal epithelium, is open to the same objection, for this, also, assumes the existence of a precedent corneal ulcer. The view long held, that conditions which tend to induce chronic hyperæmia of the conjunctiva favor the formation of pterygium, he thought was well established.

Assuming that this view is correct, are there reasons why a localized hyperæmia of the conjunctiva should be of frequent occurrence where pterygium usually forms, to the nasal side of the cornea? This is answered affirmatively. The close connection between the vessels of the recti muscles and those of the anterior portion of the conjunctiva were referred to, and it was pointed out that the determination of blood to these muscles might influence the blood-supply of the overlying conjunctiva, and that this would be the case especially with the recti interni, since they were the largest of the straight muscles, and in close relationship with the conjunctiva, because attached to the sclerotic nearer to the corneal border than any of the others. Abnormality in the distribution of the blood-supply of the internal recti muscles and of the overlying conjunctiva, and more frequently still, disturbance in the normal relationship between convergence and accommodation, such as insufficiency of the internal recti muscles, the different varieties of ametropia, were regarded as the usual causes of pterygium through the localized hyperæmia of the conjunctiva, to which they give rise.

RECURRENT RETINAL HÆMORRHAGES FOLLOWED BY THE OUTGROWTH OF NUMEROUS SMALL BLOOD-VESSELS FROM THE OPTIC DISC,

by SAMUEL THEOBALD, M.D., of Baltimore.

The case reported was that of a lady, fifty-two years of age, in whom menstruation had recently ceased. During a period of nine months, she had suffered with recurrent hæmorrhages into the retina and the posterior part of the vitreous humor of one eye.

The macula escaped serious involvement, and central vision was but little affected. The hæmorrhages were supposed to be due to thrombosis of one of the larger retinal veins. Finally, a nebulous outgrowth from the optic disc, extending forward into the vitreous humor for some distance, made its appearance. This consisted of numerous small and nearly parallel blood-vessels running from behind forwards, and held together by semi-opaque tissue, the outline of which could be easily distinguished from the surrounding vitreous. When last seen, this growth had diminished somewhat in size. The prognosis was regarded as favorable, the development of the vessels being looked upon as an effort of nature to repair the damage caused by the repeated hæmorrhages.

DISCUSSION.

Dr. W. H. Carmalt, of New Haven. On February 17, 1877, a gentleman presented himself to me, complaining of sudden blindness in the left eye. I found it filled with blood, which prevented a thorough examination. A month later, examination showed nothing peculiar, except traces of coagula in the vitreous. August 3d of the same year, he began to complain of affection of the other eye. On this occasion, Dr. Noyes examined the eye, and found hæmorrhages into the vitreous of the right eye. The condition cleared up in that eye, and on June 3, 1878, the left eye was again affected. These attacks have continued to recur every few months.

Dr. B. E. Fryer, of Kansas City. I would say, with reference to the cases of recurrent hæmorrhages, whether or not attention has been directed to scurvy as a cause. I have seen one case of recurrent retinal hæmorrhage, which I thought was due largely to that cause.

Dr. O. F. Wadsworth, of Boston. I have seen several cases of recurrent hæmorrhage, partly retinal, but largely into the vitreous. In only one could I positively say that there was a development of vessels into the vitreous. The other cases have not been observed sufficiently long to show whether or not there has been a development of vessels. The case referred to was that of a man seen ten years ago, when he was thirty-five years of age. When I saw him, there was extensive hæmorrhage into the vitreous of one eye, rendering the fundus invisible. This cleared up to a certain extent, leaving portions of the retina clear. Then certain changes in vessels toward the periphery could be seen. The other eye showed a perfectly healthy fundus, except in certain places toward the equator, where there were several patches of perivasculitis. The hæmorrhages continued to recur in the affected eye. After a time, there could be detected in the vitreous a nearly transparent membrane, containing vessels, some of which could be traced back to the retinal vessels. Two or three years later, I again saw the patient. He had then been free from recurrences for a year or two. There were still some vessels in the vitreous, but not so many as previously.

Dr. H. Knapp, of New York. I wish to say a word with reference to treatment. The main point is not to fatigue the eyes, and to put them at rest early in the evening. A waitress in a New York family suffered from hæmorrhages every time the family gave an evening party. She was sent to the country, and the hæmorrhages cleared up. She returned and served at an evening party, and again the eye filled with blood. She has now given up service, and for two or three months has had no trouble. The treatment consists in rest, and in avoidance of everything that would produce a dropsical condition of the blood.

EMBOLUS OF THE CENTRAL RETINAL ARTERY,

by G. C. Harlan, M.D., of Philadelphia.

The patient was a clerk, fifty-two years of age, in good general health. While reading in perfect comfort, a shadow suddenly appeared before the left eye, and, on closing the other, he could just distinguish large objects about the room "through a brownish haze," and in a few minutes, sight was entirely gone.

An ophthalmoscopic examination, made the next morning, showed an extensive œdema of the retina, giving the whole fundus a grayish tinge; disc pale, and its margins blurred; arteries very pale, although not much narrowed, and some of the smaller branches lost in the retinal œdema; larger veins contracted in places, particularly in and near the disc, but generally of full calibre; phenomenon of visible, slow, continuous circulation of blood in bead-like sections, well marked in superior temporal artery and vein; macula occupied by bright-red patch, oval in form, with its long diameter horizontal, and several minute terminal vessels in its neighborhood enlarged and apparently isolated; two small dots of retinal hæmorrhage at outer margin of disc. The œdema increased decidedly for the first few days, and then gradually subsided. There was still a little remaining on the nineteenth day, after which the patient was not seen for three weeks, when the color of the fundus was normal. The visible circulation lasted only about a day and a half, disappearing first in the artery. The veins refilled at their narrowed portions, and retained nearly their full calibre, while the arteries became paler and narrower, until only the two main trunks could be seen, and these showed white lines along their margins from perivasculitis. The spot at the macula gradually disappeared. The disc regained the distinctness of its outlines, but remained dead-white. Colored plates were shown, illustrating the first and the final appearance of the fundus.

The pathology of the case was very obscure. The heart and kidneys were normal and there was no symptom of degeneration of the arteries. A caries of the middle turbinated bone on the same side, from long-standing nasal catarrh was not thought more likely to act as a cause than would be a similar local disease in any other part of the body. The only possible causes seemed to be that some product of the nasal disease might have found its way into the general circulation and lodged in the retinal artery; that an embolus might have been formed of a fragment washed from a parietal thrombus in some distant vessel; or that the obstruction might have resulted from disease in the retinal artery itself.

Dr. David Coggin, of Salem, Mass., read a paper entitled:

CHRONIC GLAUCOMA,

describing a case, the object being to elicit discussion as to the best method of treatment.

DANGER TO IRON-WORKERS FROM THE USE OF OLD HAMMERS,

by Dr. George C. Harlan, of Philadelphia.

A hammer was shown from which a fragment had split off, injuring the eye of a workman. The constant concussion of the hammer causes it to assume a crystaline condition and become very brittle.

A CASE OF RETINITIS PIGMENTOSA TREATED ELECTRICALLY,

by MYLES STANDISH, M.D., Boston.

The patient was a woman, thirty-three years of age and was myopic 1.50 D.; she had worn glasses since she was seventeen years of age. When first seen April 14, 1886, her sight had been failing for three years and for the last three months had failed very rapidly, so that she could not go on the street alone after dark. Upon ophthalmoscopic examination characteristic patches of retinitis pigmentosa were found in the periphery of the fundus of each eye.

Her vision was right eye $\frac{1}{8}$; left eye $\frac{1}{8}$ and the fields of vision were limited to less than 20° in the vertical and horizontal axes.

The only treatment has been the use of the constant current, of such strength as could be easily borne. This has been applied once in five days during the last fifteen months. Her present vision is, right $\frac{20}{xxx}$; left eye $\frac{20}{xx}$, and the fields of vision have now vertical and horizontal axes of 70°. She now goes on the streets after dark with safety.

ASEPTIC CATARACT EXTRACTION WITH IRRIGATION,

by C. H. WILLIAMS, M.D., of Boston.

The author reported five cases of irrigation of the anterior chamber after cataract extraction with a 0.5 per cent. solution of chloride of sodium as recommended by Dr. McKeown. Instead of a syringe, a glass flask was used, bearing two glass tubes blown in the side. One of these was drawn out to a fine nozzle that could be easily inserted into the anterior chamber; the other had a rubber tube and mouth-piece attached, so that the pressure of the stream could be controlled by the operator. The flask had a capacity of 50 cc., more than enough to complete any irrigation without removing the tube from the eye. The irrigating instruments and the 2 per cent. solution of cocaine were sterilized in the steam sterilizer, and this was not found to injure the anæsthetic properties of the cocaine. The rest of the instruments and the dressings were sterilized by dry heat at a temperature of 150° cm. In order to determine the efficiency of the solution of the biniodide of mercury used for the preliminary washing out of the conjunctival sac, some experiments with plate cultures were made at the laboratory of the Harvard Medical School, through the kindness of Dr. Ernst. An equal amount of the biniodide of mercury and the iodide of potassium were dissolved in water and added to 10 per cent. nutrient gelatine, to give a series of strengths up to 1 to 5000 of the biniodide to the gelatine. Ten days after exposure to the air of the laboratory for six and one-half hours, no growth of bacteria were found on any of the plates, although on the unprotected plates exposed at the same time, there was an abundant development of colonies of bacteria. Gelatine of the strength of Panas' solution (1–20,000) was then tried, and these plates, after four days, showed an average of 1.5 and 0.8 colonies of bacteria to the square centimetre of surface in the two series of plates, while on the unprotected plates the average was 10.5. In two of the cases of extraction a suture was passed through the piece of conjunctiva above, and this held the wound well in position. All of the extractions were done without iridectomy and a layer of iodoform was dusted on the edge of the closed lids, just before applying the bandage.

DR. LUCIEN HOWE, of Boston. In regard to antisepsis, we know that different forms of bacteria have different degrees of susceptibility for different agents. When we speak of antiseptics we mean simply one remedy which has not a general effect upon fifty or a hundred forms. After we take these different forms and isolate them, our only method of experimentation is upon the lower animals, and there we have a great deal to guard against. We are not able to draw conclusions from the effects upon animals as to the effect upon man. Besides this, it is necessary to consider the part upon which the bacteria are placed.

AMERICAN NEUROLOGICAL ASSOCIATION.[1]

THIRTEENTH ANNUAL MEETING AT LONG BRANCH.

DR. LANDON CARTER GRAY read a paper on

CHOREA.

This, he remarked, had been considered as a self-limited disease of an average of ten weeks, but he considered it more serious than has been allowed; quoting 134 cases as reported on his books, 17 of which have had one relapse, four have had two, three have had two, one has had five.

In 23, the disease was distinctly chronic. The speaker then gave the statistics of the remainder; some suffering from hysteria, and some from convulsions, some also from a neurosis, two were fatal. The mortality in pregnant women he placed at 25 per cent. He considered it to be greatly increased by mental impression, ending in chronicity or cure.

One peculiar case was quoted in which red, painful spots appeared at the ankle as premonitory symptoms; the following day chorsic symptoms were shown and the painful spot had disappeared. Against the wishes of the speaker she was removed to the country, and died on the twenty-third day. Other cases were quoted as coming under his observation, and he had habitually divided them into classes: namely, those with convulsions, others of contraction of the muscles of respiration, rapid pulse, cardiac and pulmonary lesions, etc. After a careful retrospection of these cases the writer had come to the conclusion that rest, rest in bed, was the best remedial agent; this should be guided by the symptoms of the disease. Eight years ago he had concluded that arsenical treatment was the best method to be pursued, but had since discovered his mistake, and that arsenic was but temporary in its effect. In chorea he also used large doses of dyalized iron, 30 minims to two drachms well diluted; galvanism of the spinal cord also being of benefit. The speaker also drew attention to atmospheric influences in these cases as previously mentioned by Weir Mitchell.

DR. STARR asked Dr. Gray as to the probability of adults becoming insane after developing chorea, as in some cases he had noticed a tendency to mental impairment.

[1] Continued from page 137.

DR. LLOYD remarked that he had noticed in a pregnant woman the tendency to this condition.

DR. DERCUM asked if he had had any experience with cimicifuga, also as to those cases of chorea accompanied with epilepsy.

DR. MILLS was in favor of rest, rest in bed, the child to be allowed to have her playmates come into the room and amuse her.

DR. HAMMOND thought there was a great division of opinion as to the application of arsenic, but in his own practice he used it almost exclusively, and in anæmic cases combined it with rest and tonic treatment.

DR. SINCLAIR thought that in these cases there was more or less mental impairment; he had used arsenic and pushed it to toxical effects. The speaker drew attention to heart lesions in these cases.

DR. EDES mentioned cases which had passed into insanity, but had afterward recovered.

DR. GRAY, in conclusion, considered choraic insanity of very rare occurrence; as to whether the choraic patient was more prone to insanity, that he could not say. He had not had much experience with cimicifuga.

AFTERNOON SESSION.

DR. DERCUM, of Philadelphia, Pa., read a paper on

TWO CASES OF HEMICHOREA ASSOCIATED WITH BRIGHT'S DISEASE.

The speaker called attention to the fact that the movements first commenced in the arm, next involving the face, finally the whole body; this condition remained for two weeks, the motion so violent as to interfere with sleep, carbuncles also appearing on the back of his neck, death finally resulting.

At the post mortem the vessels were found to be thickened and somewhat pale.

The second case was that of a carpenter, sixty years of age, who had suffered from vertigo for several years; suddenly one day he lost the use of his right leg, which lasted for two weeks; he was perfectly conscious during the attack, and had no recurrence. He afterward fell a few feet down a scaffold but escaped without injury; unfavorable symptoms afterward followed, and albumen and casts were found in the urine.

The writer asked if there was an association of hemichorea with Bright's disease? In this case there was no history of hemiplegia, as also in the first case. If the chorea is associated with Bright's disease why should it be so limited? He quoted various experiments in the ligation of arteries which had been made for scientific purposes, and as producing convulsions in which there was no lesion of the brain, mentioning cases of uræmic convulsions quoted in medical journals, and considered it important to note that uræmic hemiplegia is not limited to old people.

DR. EDES thought that these symptoms were not alone confined to Bright's disease, but that the general system was involved, that there were cases of hemiplegia which come and go very rapidly. He thought, in Dr. Dercum's cases, there was some disturbance in the circulation, but not enough to be detected after death.

DR. MILLS was rather inclined to agree with Dr. Edes, and to think that the disease produces unilateral depression of the general nervous system; he had seen not a few cases in which hemiplegia was developed in Bright's disease; he considered this to spring from a condition purely local, developed in the cerebrum from the uræmic poison; and at the post mortem, unless under the most careful examination of the brain, he would find nothing that he could call a gross lesion. In general terms you have an interference of circulation; why it should be right in one and left in another he did not know, and considered it purely accidental. He thought chorea might be produced in this way.

DR. DERCUM remarked that although he had made careful microscopical examinations, he had found nothing but general œdema, and in one case slight sclerosis of the vessels, but not more marked on one side than the other.

DR. E. C. SPITZKA, of New York, read a paper on

ACUTE OR GRAVE DELIRIUM.

The speaker considered that this condition might arise from various causes, commencing with insomnia, inability to collect the thoughts, and a feeling of impending misfortune. Some may feel hilarious, some have illusions of hearing or touch, others again are passive. Both the temperature and pulse increasing, the symptoms denoting extreme exhaustion; but just previous to death the patient may become sane. The reader entered into the pathological condition of the brain as described by other authors; his object being to prove that this condition was entirely due to disturbed brain circulation, produced by morbid changes in the brain and perverting the function of this organ.

DR. GRAY remarked that among his own cases coming under this head he had only had one fatal; one case had now been living three years, and was in an asylum, another case he knew lived for six months; one case had a history of syphilis. The fatal cases that he had seen had been so violent that they had to be restrained.

DR. MILLS stated that in three cases of so-called hysterical insanity two of them died and one recovered; he believed that two of them were cases of grave delirium.

DR. HENRY HUN, of Albany, N. Y., presented a paper on

GLIOMATOUS HYPERTROPHY OF THE PONS.

This he considered as of rare occurrence; the case was marked with increased incordination of movement, bulbar paralysis and general motor paresis. On the father's side nervous trouble existed. The patient was well nourished, had difficulty in balancing herself, speech drawling, the mouth being kept open generally, difficulty in swallowing and drools when eating. Her gait resembled that of a drunken man, and her arms were very weak. There was no disturbance of sensation in any part of the body.

These symptoms steadily increased up to the time of her death; there was in the later stages a decided increase in the size of the head with pain in the occipital region, but her intellect appeared clear up to the time of her death.

At the autopsy the bones of the skull were found to be rather thin; increased sub-arachnoid fluid with an œdematous condition of the brain-tissue: the pons varolii being greatly enlarged and replaced by a tumor, apparently a glioma, appearing like a greatly hypertrophied pons; a little posteriorly was a small focus of softening.

The speaker remarked that the tumor in its growth produced no symptoms of irritation; there were no convulsions and but little headache; there was simply a steady decrease of loss of function of those nervous elements which were subjected to the pressure of the growing tumor. He thought it remarkable that notwithstanding the great amount of œdema, and an internal hydrocephalus so extensive as to cause a perceptible enlargement of the head, consciousness and even intelligence were preserved up to the end of life.

DR. STARR read a paper

ON PARAMYOCLONUS MULTIPLEX.

The case alluded to was that of a grocer who previously enjoyed good health, but had recently strained himself in lifting a box. The pain commenced below the right shoulder, and was so severe that he immediately consulted a physician, and, while in his office, was seized with a convulsion, screaming with pain. This was followed afterward with spasms of the muscles of the trunk, having ten or twelve attacks in twenty-four hours, groups of muscles of the extremities gradually becoming affected, spasm of the diaphragm being also observed. These spasms he could not control, and any exposure to shock would produce them, being more liable to occur under mental excitement. Pressure on the right shoulder, at the seat of pain, would produce them at once. In this case, the spasms of the muscles were very violent, but did not move the joints.

The writer remarked that tapping of the skin would produce a spasm, and he considered this a functional neurosis. This, he believed, made a number of ten reported cases. The disease being a spasmodic affection of the muscular system, occurring bilaterally, a series of violent chronic spasms occurring at intervals after violent physical or mental strain. Galvanism, arsenic, chloral, etc., were found beneficial in the disease.

DR. SPITZKA mentioned a case in which the patient was not quite equally affected on both sides of the body. The movements here were one hundred and forty-five to the minute.

DR. DANA mentioned a case in which the movements of the muscles commenced at five, and increased to sixty, but it did not resemble Dr. Starr's description in all points.

DR. MILLS could not see the necessity of dividing this from muscular tremor, and making it a separate disease, and thought it might be of interest for Dr. Starr to give the differential diagnosis.

DR. SACHS said he did not think Dr. Starr wished to claim it as a distinct disease, but to give it a distinctive name as a subdivision. He was rather in favor of this idea also. The speaker considered there were a sufficient number of these cases to warrant this subdivision.

DR. LLOYD remarked that he had seen a number of cases of hysterical tremor which so closely resembled the symptoms mentioned by Dr. Starr, that he was inclined to believe there was hysteria in his case also.

DR. STARR, in conclusion, stated that the points in these cases were bilateral. In the case mentioned, there was a slight sound emitted. He could not agree with Dr. Dana's statement as to these being cases of convulsive tremor. He regarded the remarks of Dr. Mills as important, as it was a question in his own mind as to whether the case was hysterical or not. This same question has come up with a number of different authors.

(To be continued.)

SOCIETY FOR INTERNAL MEDICINE, OF BERLIN.

MEETING, May 16, 1887.

Discussion of paper of DR. FRAENTZEL on the use of

CREOSOTE IN TUBERCULOSIS PULMONUM.

DR. PAUL GUTTMANN said, in substance, as follows: We were led to make some experiments with this remedy from the favorable reports of the action of creosote in tuberculosis pulmonum, by Dr. Fraentzel and similar reports of Sommerbrodt, of Breslau. The report of the latter giving the result of the trial of the remedy upon 5,000 patients was published during the last month in the Berliner Klinische Wochenschrift. The decision to use creosote in phthisis pulmonum is reasonable, because this remedy acts antiseptically, and as I will presently show, very strongly antiseptically.

Koch has already observed that if some creosote be added to the culture glasses, the tubercle bacilli cease to grow. Dr. Fraentzel declared this some years ago, in the discussion at the Congress fuer Innere Medicine at Wiesbaden.

Now as to the question whether this remedy by internal use will cure or improve in a disease caused by a micro-organism. We must know not only that it works antiseptically, but how strongly as an antiseptic it will act. Such investigations concerning the action of creosote have not been made. The speaker had experimented upon a number of micro-organisms in a very simple and exact method. This consists in taking a certain amount of gelatine, mixing therewith a certain amount of creosote and placing in this mixture culture micro-organisms. The gelatine was rendered liquid by heat, then a five per cent. alcoholic solution of creosote was added, until mixtures were obtained of the strength of 1 to 4,000, 1 to 2,000, 1 to 8,000, etc. Of 17 different micro-organisms, of which 13 were pathological, 4 not pathological, 13 did not grow any more in gelatine which contained creosote 1 to 2,000, and many of them not in a 1 to 4,000 per cent. Of the remaining three kinds one still grew in a solution of 1 to 1,000. This could not be due to the alcohol, for the micro-organisms still increased, and just as fast, when alcohol, even in stronger quantities was added to the gelatine.

The author in five weeks past had used creosote in 52 cases of phthisis pulmonum, some cases light, some advanced. The mixture used was as follows: 1 part creosote, 2 parts aether acetic, 2 parts tinct. aromatic, 25 parts syrup simple, aquæ. q. s. ad 100. This is not entirely clear. After long standing the creosote settles to the bottom, and should always be shaken before used. It tastes quite well and can be made more pleasant by the addition of a little raspberry syrup. He gives 75 grains of a 1 per cent. solution 3 times a day, so that the patient gets in the whole day two and one-fourth grains or three-fourths grains per dose. This is not half the amount given by Dr. Fraentzel; in one case he doubled these proportions.

Five weeks, are, of course, too short a time in which to come to any definite conclusion as to the real worth

of the remedy, but we can at least tell whether the desire to cough and the secretion be lessened. The reporter had not found the remedy to be as well borne as did Drs. Fraentzel and Sommerbrodt. In numerous instances nausea and vomiting occurred and it had to be discontinued. In other cases it was well borne, but the appetite did not improve. In a small proportion of patients the appetite improved quite noticeably, but not so regularly as claimed by Dr. Fraentzel. During this time some patients gained, others lost in bodily weight; in general there was no marked increase. Many cases showed an improvement in the cough and expectoration, but in the greater number none was noticed. The speaker asserted that the attention and hygiene received by patients suffering with phthisis pulmonum, effects an improvement, and this was often placed to the credit of the remedies used.

Dr. Thorner had been led to use creosote in ten cases, by the paper of Dr. Fraentzel. He found creosote to be very repulsive to patients, especially so to women during the menses, probably due to the greater irritability at that time. He gave the creosote in pill form made up with ol. menth. piperiti and sapo, 80 grains of creosote divided into 60 pills, 2 pills 3 times a day after meals. In this way it is borne very well.

Dr. Rosenheim had experimented on about 30 patients, with creosote, in the Friedrichshain Hospital. The results were as follows:

(1) Vomiting immediately after taking the remedy in 40 per cent.

(2) Severe diarrhœa in at least half the cases, even when the bowels were formerly regular; the number of movements reached 10 per day.

(3) In complaints of gastralgia and colicky pains, sometimes very severe and of longer or shorter duration.

In other cases he noticed improved appetite and improvement of an existing diarrhœa. He found it best to give the liquid in an emulsion of red wine. He also used it in balsam of tolu in gelatine capsules, after the plan of Sommerbrodt.

This was well borne, except that repeated eructating occurred some minutes after the remedy was taken.

Dr. Fraentzel said he had not claimed for creosote a specific action, but that it was an especially good tonic. If, as said before, we get 15 favorable results out of 400, we are doing well. The results are not so wonderful, but they are better than those to which we have been accustomed, and the speaker begged his colleagues to experiment further with the remedy.

Die allgemeine Pathologie oder die Lehre von den Ursachen und dem Wesen die Krankheitsprocesse. von Dr. Edwin Klebs. Erster Theil. Die Krankheitsursachen. Allgemeine pathologische Ætiologie. Mit 66 theilweise farbigen Abbildungen im Text und 8 Farbentafeln. Jena: Verlag von Gustav Fischer. 1887.

[*General Pathology or Knowledge of the Cause and Being of the Processes of Disease.* By Dr. Edwin Klebs. First Part. The Causes of Disease. General Pathological Ætiology. With colored illustrations in the text and 8 plates. Jena: Gustav Fischer. 1887.]

As is indicated in the title, this book is a comprehensive work on general pathology. It is the author's intention to treat so from the scientific standpoint, leaving its application to the practitioner and clinician. The entire work is to be in three parts, each complete in itself. The first part is of the causes of disease, that is, general ætiology; the second of the changes in the structure and composition of different tissues, pathological morphology; and the third the destruction of function, general pathology. From this it would seem that the subject is approached in quite a different way from the usual treatises.

The first part is all that is as yet published. In this the origin of disease is dealt with, and the causes ranged as either internal or external. Under the former are ranged hereditary and developmental causes, and under the latter are placed those caused by living organized beings, either plants or animals.

The diseases under the first head are but few, but this portion of the book is very interesting. The evidence, which is drawn from many cases, is graphically shown by the pedigrees of the families. For example, the occurrence of epilepsy is traced through several generations, showing a tendency to the repetition of certain diseases. Also progressive muscular atrophy and the so-called hereditary polyuria, atrophy of the optic nerve are fully considered. These chapters alone give food for reflection, especially on the possibility of propagating disease by ill-assorted marriages.

The greater part of the remainder of the book is, from the author's standpoint, to be regarded as parasites, and we have the bacterial theory in its furthest limit. He has presented this theory in a very exhaustive manner, but has failed to bring sufficient stress upon those cases where the cause is doubtful. Such, for example, as typhoid fever. Then, too, he has made no allusion into the origin of malarial fever. It is interesting to see the value of the more recent researches demonstrated another parasite than the so-called plasmodium, as an exciting cause. The work is the first systematic treatise on the subject of the day has been assigned to bacteria, it is believed by many to be entirely due to this, a mass of well-sorted information is presented which carries conviction.

Knowledge accumulates so fast that a wonderful mind to marshal all the facts in their proper place and show their bearing on each other is needed to be done more judiciously than in the past. And while we hail with delight a good mind like that of Klebs, who can handle a mass of isolated facts, we must receive his conclusions with more reservation. For while he has written many modern times we are still but in the infancy of knowledge and have not even a glimpse into the future. The book is well printed, and on paper of better quality than is usually found in medical works. The colored illustrations of the appearances of bacteria as they are seen under the microscope, with the modern methods

The results are not so wonderful, but they are better than those to which we have been accustomed, and the speaker begged his colleagues to experiment further with the remedy.

Recent Literature.

Die allgemeine Pathologie oder die Lehre von den Ursachen und dem Wesen die Krankheitsprocesse. von DR. EDWIN KLEBS. Erster Theil. Die Krankheitsursachen. Allgemeine pathologische Ætiologie. Mit 66 theilweise farbigen Abbildungen im Text und 8 Farbentafeln. Jena: Verlag von Gustav Fischer. 1887.

[*General Pathology or Knowledge of the Cause and Being of the Processes of Disease.* By DR. EDWIN KLEBS. First Part. The Causes of Disease. General Pathological Ætiology. With 66, in part, colored illustrations in the text and 8 colored plates. Jena: Gustav Fischer. 1887.]

As is indicated in the title, this book is one part of a comprehensive work on general pathology, which it is the author's intention to treat solely from a scientific standpoint, leaving its application to the practitioner and clinician. The entire work will consist of three parts, each complete in itself. The first treats of the causes of disease, that is, general pathological ætiology; the second of the changes occurring in the structure and composition of different tissues, general pathological morphology; and the third part of the destruction of function, general pathological physiology. From this it would seem that the subject is approached in quite a different way from the older treatises.

The first part is all that is as yet published. In it the origin of disease is dealt with, and this is regarded as either internal or external. Under the former are ranged hereditary and developmental diseases, while under the latter are placed those due to the action of organized beings, either plants or animals.

The diseases under the first head are comparatively few, but this portion of the book is extremely interesting. The evidence, which is very complete in many cases, is graphically shown by diagrams of the families. For example, the occurrence of bleeders is traced through several generations, then the tendency to the repetition of certain nervous disorders, progressive muscular atrophy and the like, as well as hereditary polyuria, atrophy of the retina and cataract are fully considered. These chapters cannot fail to give food for reflection, especially as to the probability of propagating disease by ill-advised unions.

The greater part of the remaining diseases are, from the author's standpoint, to be regarded as due to parasites, and we have the bacterial origin pushed to its furthest limit. He has presented the subject in a very exhaustive manner, but has failed, from his great desire to bring all under the general law, to lay sufficient stress upon those cases where the evidence is still doubtful. Such, for example, as yellow and scarlet fever. Then, too, he has made special investigation into the origin of malarial fever. It is difficult for him to see the value of the more recent work, which has demonstrated another parasite than a bacillus namely the so-called plasmodium, as an efficient cause. This work is the first systematic treatise in which the question of the day has been assigned the place to which it is believed by many to be entitled. In order to do this, a mass of well-sorted information has been presented which carries conviction with it.

Knowledge accumulates so fast that it requires a wonderful mind to marshal all the facts into their proper place and show their bearings, and nowhere is it to be done more judiciously than in general pathology. And while we hail with delight any attempt of a good mind like that of Klebs, to bring into unity the mass of isolated facts, we must accept his conclusions with more reservation. For with all the discoveries of modern times we are still but standing on the threshold and have not even a glimpse into the space beyond. The book is well printed, and the paper of rather better quality than is usually found in German medical works. The colored illustrations show clearly the appearances of bacteria as they are seen under the microscope, with the modern method of contrast staining.

Elementary Microscopical Technology. A Manual for Students of Microscopy. In three parts. Part I: The Technical History of a Slide. By FRANK L. JAMES, Ph.D., M.D. St. Louis. 1887. 107 pp.

The author of this little work on practical histology regards it as a defect that, in current text-books, technology proper and micrography — to use the author's terms — are mixed up. He has, therefore, undertaken a manual "modelled after an ideal in which nothing should be taken for granted." The present Part I "details the technical history of a slide from the crude materials up to the finished mount." The work is written in a manner which is likely to prove more attractive to the amateur microscopist than to the professional histologist. It may, indeed, be commended for several good qualities, especially for the clearness and good sense of the directions given. It will prove, we think, helpful to those who, having procured a microscope as an instrument of recreation and instruction, wish to work profitably, although they do not have the advantage of being under a competent professional teacher. The work is not suited for the needs of medical students, being less adapted for their wants than several already existing manuals. This we are obliged to say, because the author is not familiar enough with the methods of histology to have selected always for presentation those which are best. For example, he omits all mention of Delafield's hæmatoxylon, the most preferable of the log-wood solutions, nor, so far as we have observed, does he refer to Weigert's hæmatoxyline methods, which may now be considered as indispensable, even in ordinary histological work. Again, the recipes which he gives for Beale's carmine are not those which experience has led histologists to give preference to. The book is neatly printed, and furnished with a convenient and ingenious index. It may serve to further characterize the work if we add that several pages are devoted to methods of decorating the slide after the preparations are mounted.

The Diseases of the Ear and their Treatment. By ARTHUR HARTMANN, M.D., of Berlin. Translated from the third German edition by JAMES ERSKINE, M.A., M.B., etc. With forty-two illustrations. G. P. Putnam's Sons. 1887. pp. 280.

Without claims to originality this is intended as a concise, scientific handbook for the practitioner, in which what the author has found useful in his own practice is particularly and fully described, while what in otology is still hypothetical is but slightly touched upon or wholly omitted.

It is clearly written, its material is fairly well arranged for reference, and well indexed, the latter rather an unusual thing in a German work. Anatomy is concisely, but sufficiently described; physiology is all too slightly dealt with when it is remembered how important it is for understanding the results of pathological processes and how little it is understood; pathology holds an insignificant position, but, as would be expected, etiology, symptomatology and treatment receive a large share of the author's attention, and on these subjects his work has been very well done.

While the book is no substitute for some of the later text-books, and not explicit enough for the student, it is of value for reference to the practitioner who is already reasonably familiar with the subject. The wood-cuts are good as illustrations, but scarcely artistic in finish. The translation is admirable.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, AUGUST 18, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE EIGHTEENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF MASSACHUSETTS.

AFTER its separation from the Board of Health, Lunacy, and Charity, the State Board of Health was given considerably enlarged powers and duties, including the causes and prevention of infectious diseases; the suppression of nuisances, and regulation of noxious and offensive trades; collection and diffusion of information relative to industrial hygiene; the hygiene of schools and public institutions; the examination, investigation, and supervision of water-supplies, and plans or systems of drainage and sewerage; the disposal and transportation of the dead; inquiries into the causes and prevention of insanity; intemperance from the use of stimulants and narcotics, and the remedies; the protection of human life; infectious diseases of animals; the inspection of food, drugs, and other articles affecting the public health.

The report is so packed with information of the greatest use to physicians and the community in general, that we advise every one who can to read it, as any review must be entirely inadequate to do much more than indicate or summarize its contents.

In the matter of water-supply and drainage, the Board was called upon in the case of ten towns. Above the city of Lowell, the impurities in the River Merrimac have increased thirty-six per cent. from 1873 to 1886, and above Lawrence, fifty-seven per cent., thereby placing the water-supply of Lawrence near the limit beyond which the water would be unfit for drinking. It is proposed to make frequent chemical and biological examinations of these and other water-supplies.

A paper by Dr. C. F. Withington on the transmission of infectious diseases through the medium of rags, comprises sixty-five pages of the report, and deals quite thoroughly with the evidence on that subject, especially as regards this State, which uses one-third of all the rags imported into the United States. His conclusions are that small-pox has been transmitted

in a small proportion of cases by rags, but more frequently domestic than foreign; that among the rarer means whereby cholera is transmitted are textile fabrics, especially clothing infected with choleraic discharges, possibly merely packed in an infected locality, a proper distinction being drawn between clothing used, and soon to be used again, on the one hand, and on the other, rags, which are certain to have undergone a process of sorting and drying, and to have spent a considerable time in warehouse and on shipboard; that the statement that cholera has been transmitted by paper rags rests upon a solitary case, of which the details are not complete, and the facts not agreed to be trustworthy, the rags being of domestic origin, and conveyed only fifty miles; that an epidemic known as rag-sorter's disease, probably, though not certainly, anthrax, appears to have broken out on three or four occasions in European paper-mills; that authenticated cases are not to be found where other infectious diseases have been communicated by rags, and that mortality tables do not show a preponderance of these diseases in paper-making towns; that there is no evidence that rag-sorters are, except for occasional cases of small-pox and pulmonary irritation from the dust in improperly-ventilated rooms, less healthy than other persons engaged in in-door manual work; that it is a proper precaution to prohibit the landing of rags gathered at the time and in the place of an epidemic of cholera, proper care being taken that rags shipped from a non-infected port did not come from an infected locality; that paper-mills should be required to have adequate ventilating apparatus in the rag-rooms and dusting-rooms; that there should be a penalty for selling or giving away infected rags; that mill-hands should be vaccinated; that the mill is the proper place for the complete disinfection of rags in general, including domestic rags, and that disinfection or destruction of infected articles should be required, instead of advised, on the part of institutions or householders.

During the four months ending September 30, 1886, there were examined 1,468 samples of food, milk, and drugs, of which 410 of food were found adulterated or not conforming to the statutes, 221 of milk below standard, and 132 of drugs not up to the requirements of the law, suspicious articles being, for the greater part, selected for examination, a very great improvement having taken place, especially in milk, since the law went into effect. There were twenty prosecutions and seventeen convictions during the four months.

Under the "Health of Towns," it appears that there were only three cases (and one death) from small-pox during the year, and that malarial fevers prevailed in fifty-nine out of two hundred reporting cities and towns, no less than "more than four hundred cases" having been returned from Framingham alone.

The report closes with an admirable manual, containing the statutes relating to the public health, and the decisions of the Supreme Court of Massachusetts relating to the same.

IS GENIUS A NEUROSIS?

THE saying of Pope: "True wit to madness is allied," has been the text of many a profound dissertation on the insane peculiarities of men of genius.

Dr. James G. Kiernan has written an article in the *Neurological Review*, in which he combats the view that genius is the product of a morbid mind. In exceptional instances where the two co-exist, he says, the genius is evidence of a healthy conservative element struggling with the incubus of disease. The best balanced poets have been the greatest. Shakespeare's works are evidence of a well-balanced intellect. Nothing exists to impign the sanity of Milton, Addison, Wordsworth, Tennyson, Klopstock, Goethe, Schiller, Burger, Dickens, Longfellow, Thackeray or Bryant.

Sophocles wrote his tragedies at a great age, and his sons called him into court to have him placed under guardianship as a dement. He refuted the imputation of his mental condition by reciting "Œdipus Colonus," which he had just composed, to his judges, who thereupon pronounced him mentally competent.

While, then, the doctrine that poetic genius is an offspring of disease is easily refuted, it is no less true, as Dr. Kiernan shows, that some of the most celebrated lights in literature have been men of more or less unbalanced minds. Poe was a dipsomaniac, and the *mental realization* of some of his poems would be counted insanity. Saxe was the victim of melancholia, the consequence of "railroad spine." Cowper was subject to periodical melancholia, and the same may be said of Byron and Shelley. Coleridge "was the prey of his own ideas, usually of outside suggestion, and for this reason his productions have a fragmentary character. He himself draws a pretty good picture of his mental condition when he says: 'Why need we talk of a fiery hell? If the will, which is the law of our nature, were withdrawn from our memory, fancy, understanding, and reason, no other hell could equal what we should then feel from the anarchy of our powers.'"

Johnson was the victim of nervous disease. He suffered from hallucinations of hearing; when he entered a doorway, he would suddenly whirl and twist about in strange gesticulations. He would often stop in the middle of the street to go through this ceremonial. He was subject to lengthened periods of mental torpor, when he hardly knew what was going on around him. Johnson inherited strong insane tendencies from his father.

Goldsmith's mental defects, Dr. Kiernan thinks, were but a slight twist in the judgment, and a blunted moral sense.

Rosseau and Pope were both the victims of the unequal development of mind and body after boyhood; they were "hebephreniacs." Both manifested suspicional delusions.

Defoe evinced insanity only as the result of age, and the same may be said of Emerson, Southey, and

Rogers, and in the case of all of these the insanity destroyed the genius.

Moliere's epileptic insanity "tinged his genial heart with sarcastic suspicion." Swift's middle ear disease caused insane suspicions and irritability. When his insanity, however, was once fully developed, his creative powers vanished.

Dr. Kiernan concludes that there is no incompatibility between poetic inspiration and the most perfect sanity, and that "the highest poetic genius is closely akin to the highest scientific, while, at the same time, much that passes for fine poetry is no better than maudlin raving, and in periodical 'insanity the appearance of poetry is often an indication for medical treatment.'"

MEDICAL NOTES.

—A case has recently been decided in one of the county courts of England in which a barber was held liable for damages for having infected a customer's face with *sycosis menti* through the use of an improperly cleansed razor.

— A curious anæsthetic used by the Chinese has recently been made known by Dr. U. Lambuth, in his third annual report of the Soochow Hospital, says *The Provincial Medical Journal.* It is obtained by placing a frog in a jar of flour and irritating it by prodding it. Under these circumstances it exudes a liquid which forms a paste with a portion of the flour. This paste dissolved in water was found to possess well-marked anæsthetic properties. After the finger had been immersed in the liquid for a few minutes it could be pricked with a needle without any pain being felt, and numbness of the lips and tongue were produced by applying the liquid to them.

—The *Medical News* says that the Exposition of the Hygiene of Infancy at Paris, was opened, on June 24th, by an address from its president, the recitation of a poem, and by music from the Guard of the Republic. It embraces all possible appliances for maintaining the lives of infants, and all substances and articles known to be of value in treating the diseases of infancy.

During the exposition open conferences will be held morning and afternoon, the first of which will be reserved for mothers. Vaccination will be performed every Monday.

— It is well known that a cold sensation reaches consciousness more rapidly than a sensation of warmth. Dr. Goldscheider, of Berlin, whose researches on the hot and cold points of the skin have gained him a well-deserved reputation, is reported in *Science* to have recently accurately measured the length of the time necessary to perceive these sensations. The observations were made on parts equally sensitive to heat and cold, and with intensities of heat and cold equally different from the temperature of the part. The time of contact was recorded electrically by means of a metallic button fixed to the skin. Contact with a cold point was felt on the face after 13.5, on the arm after 18, on the abdomen after 22, on the knee after 25, hundredths of a second. The sensation of a hot point was felt on the same surfaces after 19, 27, 62, and 79 hundredths of a second respectively. This great difference in time has an important theoretical bearing on the physiology of dermal sensations.

—The *Annals of Hygiene* cites a curious and in some cases possibly most serious blunder in the English construction of a sentence containing directions for a sanitary test. At a recent meeting of the Philadelphia Board of Health it was resolved that the agents of S. Maw, Son & Thompson, be notified that the so-called pure water test now upon the market is dangerous by reason of careless directions for its use. The test contains a poison, and under the head of directions for use is the following: "Pour a wine-glass full of water to be tested into the tumbler, then by a smart blow break the bulb at the end of the crusher. If the water remains perfectly clear, it may be drunk with safety." The person drinking it would take a poisonous dose of iodide of mercury.

—A curious outbreak of convulsionists mania, analogous to those which occurred from time to time during the Middle Ages, is reported by a foreign contemporary to have shown itself at Agosta, in the province of Rome. For some weeks past the country people have been laboring under the delusion that the district is under the immediate government of the Evil One, and before retiring to rest they carefully place on the threshold the broom and the salt, which are credited with the power of keeping off evil spirits. Many of the younger women have epileptiform attacks, during which they utter piercing shrieks, and are violently convulsed. So serious had the condition of things become, that the syndic of Agosta found it necessary to inform the Prefect, who sent detachments of soldiers into the district in order to calm the apprehensions of the inhabitants. The contrast between this strictly phyical way of dealing with the disease and the more imposing but less effectual religious ceremonies formerly employed must be interesting to historical students. As a natural consequence of this condition of mental perturbation, the country is overrun with quacks who claim to possess the only infallible remedy for the seizures. One of these nostrums, the vendor of which was making a rich harvest from its sale, was found on analysis to consist of earth, snuff and borax. Three medical men who were commissioned to investigate the cause and nature of this extraordinary affection, came to the conclusion that it was an epidemic of hysteria. They examined a number of the sufferers, mostly young women, some of whom were alleged to have vomited nails, horseshoes, and other equally indigestible substances, while others barked like dogs. Several of them were removed to Rome for treatment in the hospitals there, and measures have been taken to check the spread of the mischief. In a milder degree, this contagious form of hysteria is not infrequent, especially in places where ignorance and superstition favor

manifestations of nervous disorder. The worst excesses of popular outbreaks, like the French Revolution, have been attributed to similar influences, and with every appearance of justice.

NEW YORK.

—The American Association for the Advancement of Science has been holding its annual meeting at Columbia College during the past week, and the attendance has been very large. On the opening day an address of welcome was made by the Rev. Dr. F. A. P. Barnard, President of the College, and the general secretary announced that since the meeting at Buffalo, last year, over two hundred members had been added to the Association, while some two hundred papers had been submitted to be read before the different sections. Among the papers read was a valuable one by Dr. D. G. Brinton, of Philadelphia, Chairman of the Section of Anthropology, entitled "A review of the Data for the Study of the Prehistoric Chronology of America," in the course of which he said that in the Trenton gravels and in other localities, genuine paleolithic remains had been found which put man in America at a date cœval with the close of the glacial epoch, if not earlier. The vast antiquity of the American race was further proved by the extensive dissemination of maize and tobacco, tropical plants of Southern Mexico, which were cultivated in remote ages from Canada to Patagonia. There were, he said, about two hundred radically different languages in North and South America. Such a confusion of tongues could only have arisen in hundreds of centuries, and the study of these languages and the gradual growth of their dialects supplied valuable data for the ancient history of the Continent. The American race was distinctly a race by itself, and the oldest crania, collected from the most ancient quaternary deposits, were thoroughly American in type. As the discovery of implements in glacial deposits fixed man on this continent at least at the close of the glacial epoch, this carried his residence here to about 35,000 years ago. But there was no likelihood that he originally came into being in America. More probably he migrated along the preglacial land bridge which once connected Northern America with Western Europe; and later other tribes no doubt came from Asia.

On the second day, Dr. William Thompson, Professor of Ophthalmology in the Jefferson Medical College, Philadelphia, read a paper on "Color-Blindness among Railroad Employees," in which he said that the conflict between the officers and the employees of the Reading Railroad, which has occupied the attention of the public, and threatened to produce a suspension of work on that road, had reopened the question of color-blindness. In July last, 25,158 employees were examined on lines east of Erie, of whom 181 were color-blind, 661 had defective vision, and 158 had defective hearing. The officers of the Pennsylvania Railroad and other railways had now adopted Dr. Thompson's system of examination.

Prof. Alfred H. Leeds, of the Stevens Institute, Hoboken, read a paper on the "Causes, Progress, and Cure of the Recent Great Outburst of Typhoid Fever at Mount Holly, New Jersey." The outbreak, he said, was due to the pollution of the water-supply of the place by the defective sanitary arrangements of a large boarding-house. The purification of water could be accomplished economically by the addition of alum, which destroyed bacteria, and where water so treated had been filtered, it was found to be clear and wholesome. Professor Leeds also read before the Section on Mechanical Science and Engineering a paper on the "American System of Water-Purification," the distinctive features of which are: (1) Artificial aëration under pressure; (2) precipitation of dirt, sewage, hardening constituents, and coloring matters by harmless precipitants; and, (3) mechanical filtration through filters capable of rapid reversal of current, and cleansing by mechanical means.

Much interest was felt in two papers on the food question, which were read before the Section on Economic Science and Statistics by Prof. W. O. Atwater, and which are to be published in the *Century*. The first was on "The Physiological and Pecuniary Economy of Food," and the second on "The Food of Workingmen, and its Relation to Work Done." On the evening of August 11th, a brilliant reception was held at the Metropolitan Opera House, and the week's programme also included excursions up the Hudson and to the city institutions along the East River.

DEATH BY DECAPITATION.

IT is probably due to the fact that the prescribed methods in France for executing the death-penalty offer peculiar facilities to scientific investigation, rather than to any predilection for the grimmest of all studies in experimental physiology, that our French confrères have reported so many observations on the nervous and other phenomena of the first few seconds after sudden death. The latest observations by Drs. Regnard and Loye, in the *Progrès Médical* of July 9, and the *British Medical Journal* of July 23, enforce the fact that death by the guillotine is quite another thing than that method employed judicially by the Anglo-Saxon race. The examination was made of the head and body of a convict immediately after his decapitation by the guillotine. The prisoner was calm to the last, and not pale, even when his neck was fixed ready to receive the fatal knife. Two seconds after decapitation the cheeks were still rosy, the eyes wide open, with moderately dilated pupils, the mouth firmly closed. No fibrillary contractions could be observed. When a finger was placed close to one eye, no change of expression took place; but on touching an eye or the tips of the lashes, during the first five seconds, the lids closed just as in life. This reflex action could not be elicited from the sixth second after decapitation. The jaws were tightly clenched, and could not be opened by manual force; no similar muscular contraction could be detected in the trunk or extremities. One minute after death the face began to turn pale, the trunk remained flaccid,

the carotids continuing to throw out blood remaining in the circulatory area. At the end of four minutes the face was quite pale, the upper lids were half closed, the jaws less firmly clenched than before. Irritation of the cut surfaces of the spinal cord failed to produce reflex movements either in the trunk or on the face. For twenty minutes there was no change; then the necropsy was begun. There were signs of old pleurisy and alcoholism. The heart beat actively. On opening the pericardium, the ventricles and auricles continued to pulsate for twenty-five minutes; the former then ceased to beat, but the auricles went on for forty minutes longer. Thus the heart beat for an hour after decapitation. Then its chambers were laid open; the left ventricle was firmly contracted, the right relaxed. There was emphysema at the edges of the left lung, as is nearly always observed after death by the guillotine. There were bubbles of air in the vessels of the pia mater, and much air in the subarachnoid space. The knife had passed through the lower part of the fourth cervical vertebra. These researches show that not a trace of consciousness remains two seconds after beheading; that reflex movements of the cornea can be excited for a few seconds; that the heart may beat for an hour, the auricles continuing to pulsate alone for over half that period; and that, putting aside the reflex movements of the eyelid, the contraction of the jaws and the jets of blood from the carotids, it seemed in this case as though a corpse had been decapitated, so inert were the remains of the convict. The entry of air into the inextensible and incompressible cranial cavity, after the escape of blood from its vessels, was only to be expected. Drs. Regnard and Loye note how calm and free even from physiological death-struggle symptoms is death by the guillotine. There is not even asphyxia; death is rather due to inhibition similar to that described by M. Brown-Séquard in animals who succumb to certain irritations of the nervous system.

Correspondence.

THE OUNCE TROY AND THE OUNCE AVOIRDUPOIS. CORRECTION.

Trenton, N. J., August 12, 1887.

Mr. Editor,—Either through my mistakes or those of your printers, my letter to you as printed last week, is particularly unintelligible. The second paragraph should be as follows:

One ounce Troy (℥) is equal to one ounce avoirdupois and 42.5 grains over; and the one-eighth ounce bottles of the wholesalers contain not *one drachm* (℥) but 54.7 grains Troy; and if Dr. Morse's calculations are made on the *one drachm* (℥) basis his patient took, not 51 grains of morphia, but about 45.7 grains.

If you deem it of sufficient importance, please make the correction and oblige, Yours very truly,

Horace G. Wetherill, M.D.

Deaths reported 3,187: under five years of age 1,015; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 1,083, consumption 253, lung diseases 90, diarrhœal diseases 839, diphtheria and croup 77, typhoid fever 76, whooping-cough 29, malarial fever 22, measles 15, scarlet fever 15, cerebro-spinal meningitis seven, erysipelas two. From whooping-cough, New York nine, Philadelphia seven, Baltimore and Milwaukee four each, Boston three, Pittsburgh two. From malarial fevers, New Orleans eight, Philadelphia, Brooklyn and District of Columbia three each, Nashville and New York two each, Baltimore one. From measles, New York five, Philadelphia four, Baltimore and Pittsburgh, two each, Milwaukee and Fall River one each. From scarlet fever, New York seven, Philadelphia four, Brooklyn and Boston, two each. From cerebro-spinal meningitis, New York, three, Milwaukee two, Fall River one. From puerperal fever, Philadelphia two, New York, Baltimore, Pittsburgh and Milwaukee one each. From erysipelas, Philadelphia and New Orleans, one each. From small-pox, New York one.

In the 20 cities and greater towns of Massachusetts, with a population of 940,875 (population of the State 1,941,465) the total death-rate for the week was 30.01 against 32.86 and 27.41 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending July 23d, the death-rate was 22.2. Deaths reported 3,937: infants under one year of age 1,597; acute diseases of the respiratory organs (London) 174; diarrhœa 100, whooping-cough 162, measles 100, scarlet fever 54, diphtheria 29, fever 27.

The death-rates ranged from 11.7 in Derby to 36.7 in Preston; Birkenhead 27.2; Birmingham 16.1; Hull 15.1; Leeds 22.5; Leicester 32.4; Liverpool 24.1; London 24.5; Manchester 23.4; Nottingham 17.7; Portsmouth 13.2; Sheffield 18.6; Sunderland 15.7.

In Edinburgh 18.8; Glasgow 21.5; Dublin 29.9.

The meteorological record for the week ending August 6, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Aug. 6, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

FRACTURE OF THE SPINE: ITS IMMEDIATE TREATMENT BY RECTIFICATION ON THE DEFORMITY AND FIXATION BY PLASTER-OF-PARIS JACKET.[1]

BY HERBERT L. BURRELL, M.D., OF BOSTON.

From a practical point of view, we may consider dislocations and fractures of the spine together, and it will not be a difficult task to represent to the minds of most surgeons the utter hopelessness of this injury in most cases.

All authorities[2] agree that the prognosis depends largely upon the location of the injury, and the amount of damage done to the spinal cord. It is not the injury to the bony structures or ligamentous union, that renders this injury so fatal, but the pressure or crushing that takes place, of that wonderfully constructed spinal cord, which receives and transmits impressions to the various members of the body.

The spine itself is so complexly constructed, adapted to so many different movements and purposes, that we can really say, that when it receives an injury, the "back bone" of the human organism is broken.

The cord resting as it does in a bony canal, may be pressed upon by bony spiculæ from any side, it may be pressed upon or severed completely by some sharp fragment, or simply the anterior buttress or body of the vertebræ may be crushed upon itself, without any serious or permanent injury to the cord having occurred. This is illustrated in Plate VIII.

The higher the injury of the bony column, the greater fatality. Gurlt[3] reports that out of 178 cases where the cervical vertebræ were fractured, death occurred in 164, or 90¼%. Out of 184 in the dorsal region, death occurred in 146, or 79¾%. Out of 82 in the lumbar region, death occurred in 56, or 68⅓%. This ratio of mortality is quite what we should expect, as the nearer we approach the respiratory centre, the more fatal is the injury.[4]

By the courtesy of the surgeons of the Boston City Hospital, I have been enabled to collect all the cases (82) that have occurred in that Hospital, and have tabulated them, to ascertain what facts they will show. The lines represented in the next column present a synopsis of the detailed account that appears in the tables.

First, regarding the mortality of these cases, we find that the fatality is very great, and this is represented by Table A 1.

The fatality I have further analyzed to show mortality according to location. This is represented in Table A 2.

The striking immediate fatality of the accident is shown in Table A 3.

The recoveries have been divided into two classes: the first, where the patient was useful, in the sense of being self-supporting; the second, useless, where the patient is bed-ridden, and unable to earn a livelihood. So that we really have in these 82 cases of Fracture of the Spine, an apparent recovery of 22%, where really there is only 11% returned as producers in the community. This is shown in Table B.

The ratio of frequency of prominent symptoms occurring after fractures of the spine, is shown in Table C.

The utter hopelessness which is expressed in the term broken back, pervades the minds of all practitioners, and perhaps Erichssen[5] expresses the general feeling, when he says that "Fractures of the Spine through the bodies of the vertebræ with displacement, are inevitably fatal."

The treatment of fractures of the spine may be divided into three principal heads:—

(*a*) Expectant. Water bed. Air bed. Wire bed. Bonnet's vertebral gutter. Extension and counter-extension.

(*b*) Operative. Trephining. Removal of bony fragments.

(*c*) Rectification of the deformity and fixation of the spine by plaster-of-Paris jacket or other apparatus.

(*a*) *Expectant.*—The statements made by Cline[6] and by Cooper[7] that we can accurately determine whether the body, or the arch, or the spine of a vertebræ is broken, is not supported by facts. Further,

[7] Sir Astley Cooper on Dist. and Fract., 1851, p. 479.

Cline and Cooper believed that death was inevitable, sooner or later, if the fragment were not lifted by an operation.

This is possibly true, but specimens like Plate I and Plate II, show only too clearly that, at times, we have to do with an irremediable injury, and our duty in such cases is to pursue the expectant plan of treatment — that is, placing the patient on an air or water bed, and treating the symptoms as they arise. By this means we can prolong life, and make existence bearable. It is possible that a certain amount of relief may be obtained in these severest cases by permanent extension and counter-extension.

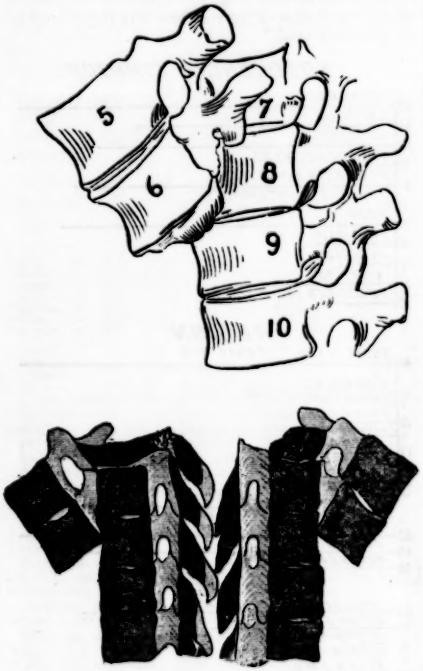

PLATE I. (No. 1229, Warren Museum.)
The patient fell 30 feet. Wild and irritable, complete paralysis, bed sores, cystitis, and death from exhaustion in two months. There has been a complete rupture of the intervertebral substance between the 6th and 7th vertebræ, the upper edge of the 7th being carried away to the right side with the 5th and 6th vertebræ. The state of the spinal cord in this case may be imagined.

Having decided that the expectant plan of treatment must be pursued in certain rare cases, we come to our second division, that of

(*b*) *Operative.*— What further can I say to you than has been said in that bitter controversy between Sir Charles Bell[8] and Sir Astley Cooper, as to the expediency of operations on the spine. Only on the parts posterior to the spinal cord, could an operation for a moment be entertained; for to attempt to remove the body of a vertebra after fracture of the spine from behind, would necessitate the division of the spinal cord; to attack it in front would be equally inadmissible, for the thoracic viscera, aorta, solar plexus, and vena cava would forbid; and an attempted removal from the side would be equally inexpedient.

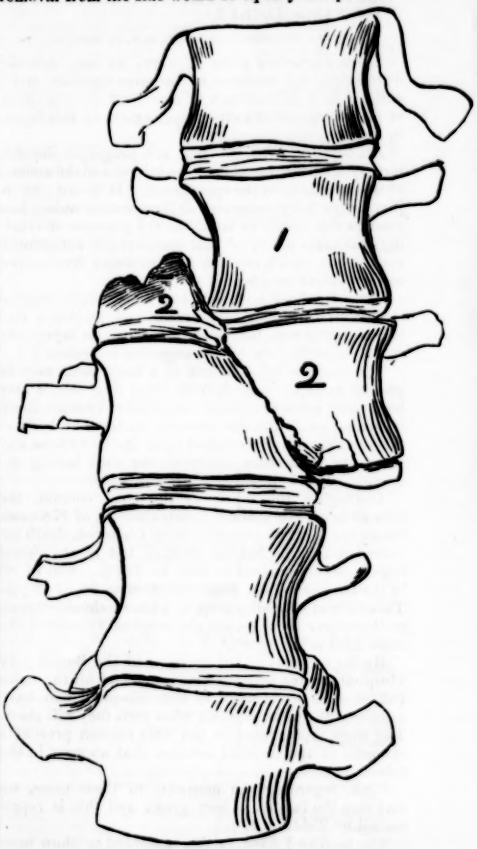

PLATE II. (No. 139, Warren Museum.)
T., æt. 19, run over by a fire engine. Complete paralysis, bed sores, cystitis, and died of exhaustion. There is a very extensive fracture and displacement of the 1st and 2d lumbar vertebræ. Cord completely destroyed.

Five cases have been operated upon at the Boston City Hospital. All ended fatally.

It may be of interest to see the status that this procedure should occupy in surgery. Paré, Heister, and many of the older authors discussed the propriety of excising portions of the vertebræ or trephining, but Henry Cline[9] first performed the operation at St. Thomas's Hospital, June 16, 1814. The patient lived seventeen days, and Mr. Cline admitted that the operation hastened the end. Lidell[10] failed to find a

[10] On Injuries to the Spine. American Journal Medical Sciences, October, 1864, Vol. XLVIII, p. 320.

single well-authenticated successful case. It is certainly true that Legoust,[11] Jobert,[12] E. Gurlt,[13] Hamilton,[14] and Sir Charles Bell [15] all condemn the operation in unqualified terms.

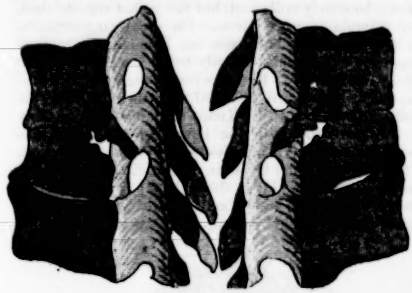

Plate III.

Gun-shot injuries, however, may be excepted from this sweeping condemnation, and all the reported successful cases of operation closely resembled that done by Louis [16] in 1762, where bony fragments were removed after a gun-shot fracture of the spine.

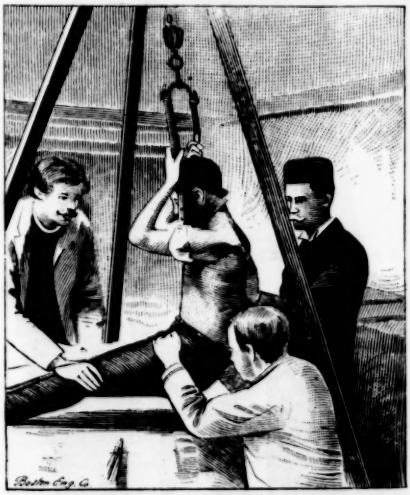

Plate IV.

The removal of fragments after gun-shot injuries to the spine is perfectly justifiable, and will, I believe, give a fair measure of success. In the War of the Rebellion,[17] "there were twenty-four cases of removal of fragments of the vertebræ after gun-shot fracture, with fatal results in only ten instances." In nine instances, however, of the fourteen examples of recovery, the spinous process, or fragments of it, only were removed. In the five cases of recovery, in which portions of the laminæ or the transverse processes were removed, the results were much less satisfactory, nearly all of the patients having serious disability.

On the other hand, the operating on fractures of the spine, not compound, is not a justifiable measure, and without further evidence supporting this operation, it will have to be placed among the impracticable efforts of experimental or venturesome surgery.

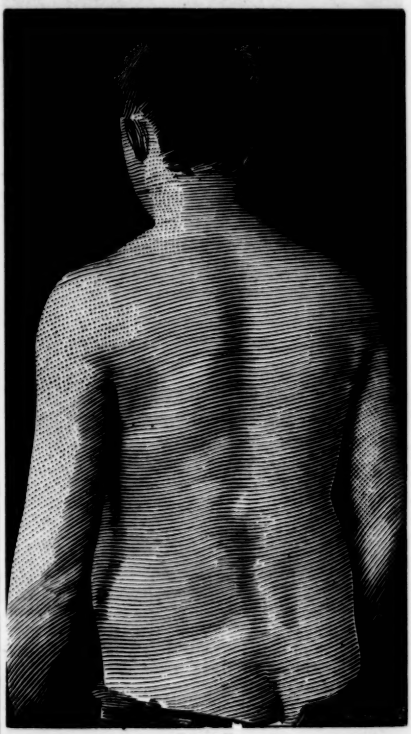

Plate V.

(*c*) *Immediate Rectification of the Deformity in Fracture of the Spine and Fixation by Plaster-of-Paris Jacket.* On the 10th of August, 1886, I saw the autopsy of a woman who had been under my care, with a fracture of the spine, in the Boston City Hospital (Plate III, Case 78), and found that a plate of bone from the posterior wall of the body of the twelfth dorsal vertebra had been broken off, in addition to an arching backward of the whole spine. This plate had pressed upon the cord, and had, in thirty-eight hours, led to red and white softening for a distance of fifteen mm. The presence of the plate

[17] Hist. of the War of the Rebellion, Part 1, Surg. Vol., p. 459.

anterior to the cord showed me that an operative procedure would have been of no avail, and the *softening* occurred so early in the cord, led me to believe that, if aught was to be done to remedy the damage caused by a fracture of the spine, it must be done at once.[18]

The arching of the vertebræ suggested that the difficulty might be overcome by *immediately* pressing back the deformity, and fixing it in this corrected position.

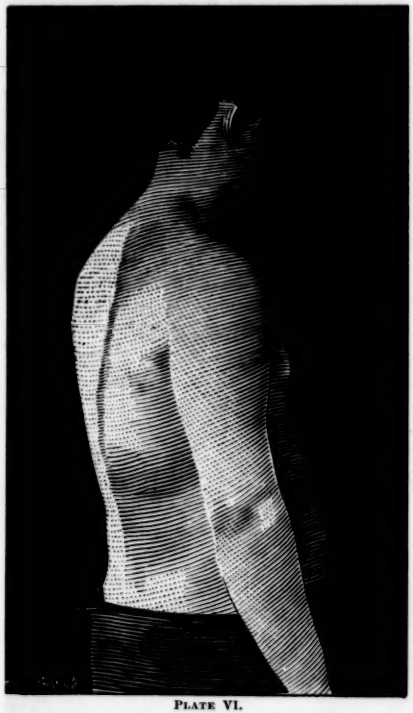

PLATE VI.

I determined to act upon this principle in the next case. On August 24, 1886, Case 17 was admitted, and was seen within twelve hours of the time of his fall of forty feet. The risks of immediate rectification and suspension having been explained to him, he was suspended, as represented in Plate IV, with this difference, that the tripod was placed over the head of the bed, a ward-master was placed upon a small table at either side of the patient, to lift up on the body at the axillæ. This, when one has many assistants, is a great aid to the patient. The back of the patient, while being changed from the horizontal to the perpendicular position, should be carefully supported, and when the patient is brought into an erect position, the buttocks are free from the table.

The deformity, which was at an angle of at least 30°, included the twelfth dorsal vertebra, was reduced, and a plaster-of-Paris jacket was quickly applied. An anæsthetic was not given, for I did not wish to have any danger masked. The patient's sufferings during the suspension, rectification, and application of the jacket were more intense than anything I have ever seen; he nearly collapsed, but the jacket was finished, and stimulants were given. On recovering himself, he said that there had been an immediate return of sensation in his limbs, directly following the reduction of the deformity. His recovery proceeded uninterruptedly. On April 23, 1887, for the first time, he walked out. Dr. P. C. Knapp examined him on May 1, 1887, and found in the left thigh and leg no galvanic reaction. All muscles react to faradic current. The right thigh and leg have no faradic reaction. He now walks with a halt in the right leg, and on May 5, 1887, was found acting as a bar-tender. Plates V and VI represent his present condition.

PLATE VII. (No. 140, Warren Museum.)

Fracture of 12th dorsal, with displacement; extensive laceration of inter-vertebral substance; cord almost completely severed; death, 9½ weeks; paralysis, bed sores, cystitis.

This procedure, at the time, I supposed to be an original thought, but soon found that other gentlemen in the same hospital had preceded me.

Five cases have been treated in this manner in the hospital to a completion. Dr. Wm. Ingalls on April 6, 1884, applied a jacket to a fractured spine, the deformity having rectified itself by suspension, but his

[18] Case 80. Red Softening in Cord. Death in eighteen hours.

patient unfortunately died. Dr. W. P. Bolles, on July 15, 1884, applied a splint of plaster-of-Paris at once to a fractured spine, and his patient recovered, but is useless. Dr. M. F. Gavin, on September 21, 1886, rectified the deformity in a fractured spine, having suspended a patient weighing over 200 pounds. Great dyspnœa and pain occurred. The jacket did absolutely no good, requiring to be cut up on the second day, and gaped nearly an inch. The patient died in two months, of exhaustion.

On November 26, 1886, by the courtesy of Dr. Gavin, I was again enabled to attempt the rectification of a fracture of the tenth dorsal vertebra, and applied a plaster-of-Paris jacket; this case was seen a short time after the fracture occurred. There was no paralysis, and the patient made a good recovery.

Of these five cases two have died, one is useless, and two have recovered.

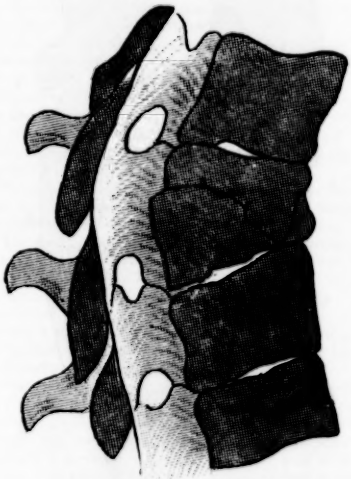

PLATE VIII. (No. 1376, Warren Museum.)
Diagram of a fracture of the body of a vertebra, not narrowing the canal materially.

Of the expediency of rectification of the deformity I can but think that an important lesson can be learned from a study of these drawings of specimens from the Warren Anatomical Museum. Plates I and II show that any efforts would be futile; while Plates VII, VIII, IX, X, and XI, are very suggestive as to the possibility of immediately rectifying the deformity.

The application of the plaster-of-Paris jackets for fracture of the spine is by no means a new idea, and the literature on the subject at my command, gives me the following facts:

In the fall of 1874, Professor Sayre states that he first applied a plaster-of-Paris jacket for Pott's disease and doubtless to his bringing this method of treatment of Pott's disease [19] before the profession, is due the present application of plaster-of-Paris jackets in fresh fractures of the spine.

[19] Succinct History of the Plan of Treatment of Pott's Disease by Suspension and the use of plaster-of-Paris Bandage, p. 4.

On June 25, 1879, J. R. Weist, of Richmond, Indiana, reduced a fracture of the ninth dorsal vertebra during suspension, and applied a plaster-of-Paris jacket. This was followed by a great relief to the pain, uninterrupted improvement, and a recovery of the patient on the 67th day.

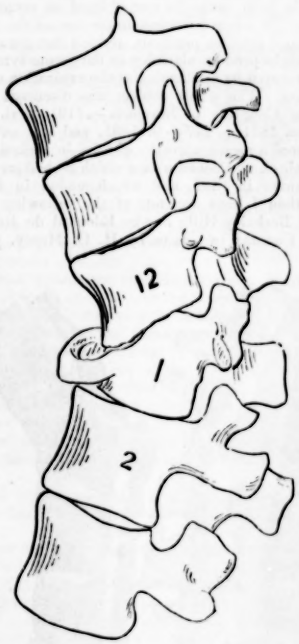

PLATE IX. (No. 941, Warren Museum.)
Fracture of 1st lumbar vert. Female, æt. 19; fall, 20 ft., striking on nates. Spinal canal encroached upon. Symptoms, — Complete paralysis, immediate. Results, — Moderate improvement after 3 weeks; power of sphincters regained.

Dr. Weist says that when he applied the plaster dressing in this case, he was not aware that it had been used in such cases; but he learned from Dr. Sayre that it had been used several times in a similar manner at Bellevue Hospital with very satisfactory results, and says that probably others also have used the plaster jacket in this way. However this may be, Dr. Weist made the report at the request of Professor Sayre, and with the exception of an allusion to a case of Spratley's by Reginald Harrison, shown at the Liverpool Medical Institution [20] Dr. Weist's case is the earliest published record of the procedure that I have been able to find.

In the remainder of the year, 1879, I find five cases treated in this manner. König, of Gottingen, in 1880, said that having used suspension and plaster-of-Paris jackets for caries of the vertebræ, where there was paralysis, with great improvement, he was led to apply

[20] Surgical Diseases of the Urinary Organs (Lectures on), p. 51, by R. Harrison, at the season, 1878-79.

a similar treatment to fresh fractures of the spine. He did not advocate its employment in all cases, but in his three cases the results were favorable.

He said that doubtless the method had been employed in other hospitals, and he wrote the paper as a contribution to the subject. Wagner, of Königshutte, reported two cases with which he was not at all satisfied. In both cases he was obliged to remove the jacket. He advised caution in the use of the jacket, had seen it produce paralysis, and felt that the replacement might produce alarming or dangerous symptoms. He advocated its application at the expiration of fourteen days. The whole subject was discussed at the German Congress of Surgeons — (19) Berl. Klin. Wochen. 1851, p. 247 — in 1881, and was evidently considered a measure worthy of trial in picked cases. Langenbeck mentioned a case which he had treated in this manner in 1862, and which ended in failure. Since then I have accounts of the following cases: One by Berkeley Hill; one by Edouard de Reynier; one by Carson; two cases by H. O. Marcy, private letter.

PLATE X. (No. 4629, Warren Museum.)
Old fracture 12th dorsal. Upper edge has been broken away from body of centrum. 12th dorsal vertebra is crushed anteriorly. Considerable narrowing of canal, opposite upper edge of 12th dorsal vertebra.
C. A., æt. 18; fell on plank floor. Paralysis, bed sores, cystitis; death after 2 8-12 years. Cord considerably disorganized at seat of injury.

No attempt has been made to investigate cases where a jacket has been applied after the tenth day following an injury. This gives us sixteen cases, in which three died, three derived no benefit from the method, and ten were greatly benefited.

The subject may be summarized, and I submit the following conclusions:

First, That, in the *immediate* correction of the deformity and fixation with plaster-of-Paris jacket or other means, we have a rational method of treating a large number of cases of fracture of the spine.

Second, That, considering the hopelessness of results in fracture of the spine when treated expectantly, almost any risk is justifiable.

Third, That the *immediate* correction of the deformity is imperative, *if* softening of the cord can and does occur from pressure, at the end of forty-eight hours.

Fourth, That the suspension of the patient is only a means of rectifying the deformity, that certain fractures could be simply pressed into position while the patient lies prone or supine.

The objections to the treatment are,—

(1) That the expectant plan of treatment gives a small percentage of recoveries.

(2) That there are serious risks, especially in the cervical region, attending the suspension of a patient and the rectification of the deformity with a fractured spine in the way of shock, collapse and death.

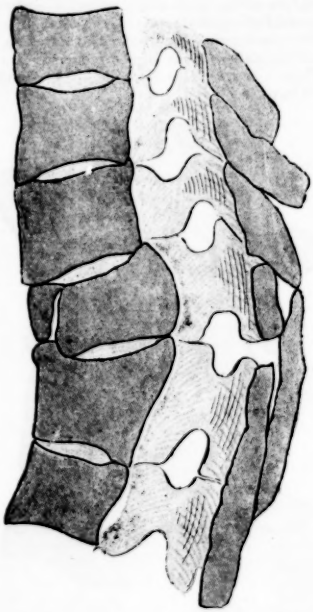

PLATE XI. (No. 938, Warren Museum.)
Fracture 4th dorsal; longitudinal section, showing backward displacement and narrowing of canal. Female, æt. 25; fall, 15 feet; paralysis (complete); bed sores; death, 9 weeks.

(3) That in attempting to relieve pressure on the cord, by rectifying the deformity, that we might either sever the spinal cord or make pressure upon it. This is a matter of chance.

My own belief regarding the status that the procedure should occupy in surgery, is: that it will occasionally be a life-saving measure; that it should be applied under anæsthesia in all cases of fracture of the spine, which are not conclusively known to be irremediable; and that apart from the chance of recovery that is offered to the patient by this means, it will almost invariably make the patient more comfortable, in that he can be handled more easily.

In conclusion, I wish to acknowledge my indebtedness to Drs. H. W. Cushing, E. G. Brackett, and W. H. Prescott, for valuable assistance rendered, in preparing details of this paper.

SEPSIS AND ANTISEPSIS IN SUMMER DIARRHŒA.[1]

BY SILAS ALLEN POTTER, M.D., OF ROXBURY.

WRITERS upon summer diarrhœa appear to be agreed that fermentation holds an intimate relation to the disease.

Dr. H. C. Haven,[2] writes, "It will, I think, be universally admitted that, in its totality, summer diarrhœa of infants is a zymotic or fermentative disease."

Maxmilian Herz[3] states in regard to cholera infantum, "It is pretty generally admitted that putrefaction of food, as Baginsky maintains, is an important cause of cholera infantum."

J. Lewis Smith[4] says of infantile diarrhœa of summer, "Undoubtedly one of the most important causes is to be found in the very free exhalations arising from decomposing animal and vegetable matter during the heated term, and the disease is always most frequently met with in those localities where the accumulation of filth is the greatest."

It is the object of this paper to collect the more important facts about fermentation, and consider their relation to the disease in question.

The terms sepsis and antisepsis we wish to employ in a broad sense, to indicate, on the one hand, injurious effects resulting from micro-organisms; on the other, influences adverse to the life or activity of micro-organisms.

The alcoholic fermentation is caused chiefly by the yeast fungus, torula cerevisiæ; the bacillus lactis is certainly one cause of lactic acid fermentation, and the bacillus butyricus is one cause of the butyric acid change in rancid butter. Of these three fermentative processes it may be affirmed that the principal organism concerned in their production has probably been determined. The organisms referred to have been isolated, a pure cultivation of them introduced into an appropriate sterilized medium, and the proper chemical decomposition obtained.

Other fermentations, such as the acetic, ammoniacal, viscous, putrid, have not been studied with the accuracy which the later methods of research permit. Though due to bacterial action, it is impossible to designate a particular organism as their sole or chief cause. The micrococci found in putrefying material are yet undifferentiated, and the bacterium termo, believed by Cohn to be the essential cause of putrefaction, has already been proved to be a name covering more than a single variety of organism. It is not improbable that the same may be shown to be the case with the micrococcus ureæ, the bacterium aceti, and others.

However, it is not so much with the particular organisms producing these changes that we are now concerned, as with the grand fact, apparently accepted by bacteriologists, that the cause of fermentation and putrefaction is vital. "Micro-organisms" writes Carl Fraenkel,[5] "are the producers of fermentation, and, what in the economy of nature is a still more important part to play, are the cause and the only cause of the putrefaction of organic substances." When it was proved that the exclusion of bacteria from a wound was what averted the traumatic infective diseases, a scientific basis was at once given to antiseptic surgery. If we believe that summer diarrhœa in a very large number of instances would not occur but for fermentation, the recognition of the cause of fermentation is the initial step toward an understanding of the disease.

The action of fermentative organisms in causing diarrhœa is probably indirect, the immediate agents being substances produced by the microbes through the decomposition of the fluids in and upon which they live.

According to Flugge,[6] the chief products of bacterial action are: gases, as CO_2, H, CH_4, H_2S, NH_3; water; sulphur; volatile bodies, as trimethylamin, alcohol, formic acid, acetic acid, butyric acid; fixed acids, as lactic, malic, succinic, oxalic, tartaric; sulphoacids, as taurin, amides of the fatty acids, especially leucin, alanin; bodies of the aromatic series, as tyrosin, phenol kresol; reduction products, as indol, hydroparacumaric acid; complex molecules, as carbo-hydrates, pepton, hydro-lytic ferments; coloring matters; and poisonous alkaloids.

Of these substances two classes, some members of which, at least, are produced by the bacteria of fermentation, are interesting in the study of summer diarrhœa: the acids and poisonous alkaloids.

Acids can excite diarrhœa by immediate irritation of the mucous membrane of the bowel, the alkaloids indirectly by systemic effect. The simpler, less violent cases of diarrhœa can often be traced to the irritation of undigested food and the acrid substances produced by its fermentation; the more sudden and violent cases often appear to call for the agency of a poison.

It was long ago noticed that serious illness oftentimes followed the eating of decomposing meat, fish or cheese.

Kerner seems to have been the first to suspect that alkaloids were formed by the decomposition of albumen, and in 1820 called attention to the similarity between the poisoning by sausages and atropia.

Panum, in 1856, demonstrated that putrefying substances often contained poisons which, when injected into animals, caused death. That death was not due to the activity of bacteria introduced into the body, he showed by sterilizing the fluid before injection. He also proved that the inflammatory changes in the intestinal mucous membrane of animals poisoned with putrid material was not caused by the bacteria in the putrid fluid but by chemical substances which retained their character even after boiling.

Solmi, of Bologna, gave to these alkaloids formed by the decomposition of proteids, the name of ptomaïnes.

Necki, in 1876, first obtained ptomaïnes in a pure form, and determined their chemical symbols.

Brieger, however, in 1885, produced the most important results which have been obtained in this branch of investigation. From putrefying meat he isolated three alkaloids which he called neuridin ($C_5H_{14}N_2$), neurin ($C_5H_{13}NO$), and cholin ($C_5H_{15}NO_2$). From putrefying fish he obtained neuridin, muscarin ($C_5H_{15}NO_3$), gadanin ($C_7H_{17}NO_2$), and a base allied to æthylendiamin ($C_2H_4(NH_2)_2H_3O$). From decomposing gelatine he separated neuridin, muscarin and dimethylamin. Of these, neu-

ridin is most constantly found in commencing putrefaction. The presence of the others seemed to depend in some degree upon the special substance undergoing decomposition. From putrefying human bodies Brieger obtained several alkaloids, neuridin, cholin, cadaverin ($C_5H_{16}N_2$), putrescin ($C_4H_{12}N_2$), saprin ($C_5H_{16}N_2$), trimethylamin ($(CH_3)_3N$), dimethylamin, triæthylamin, mydaleïn, and a substance of undetermined composition.

The physiological action of these various compounds differs widely. Some, as neuridin, cadaverin, putrescin and saprin are either harmless, or must be injected in very large amounts to produce toxic symptoms; others are violent poisons. Of the latter, there are five which bear an interesting relation to summer diarrhœa: neurin, muscarin, cholin, mydaleïn and the substance of undetermined composition. The action of the first three is essentially identical. The most important symptoms produced by a fatal dose are salivation, vomiting and diarrhœa, dyspnœa, paralysis and death. Mydaleïn, when injected into guinea-pigs, even in the very minute quantity of three-fortieths of a grain, caused profuse secretion from the eyes, nose, mouth, and intestine, dilated pupils, exophthalmos, an increase of temperature, paralysis, fibrillary twitching of muscles, dyspnœa and death. In cats the result was not essentially different, diarrhœa being prominent as before. The substance whose composition was not determined, produced in rabbits and guinea-pigs, excessive peristalsis and exhausting diarrhœa. In general, it may be said that most of the alkaloids obtained by the decomposition of albumen have a tendency to produce diarrhœa.

It does not follow that, because ptomaïnes capable of exciting diarrhœa are formed outside of the living human body, they are formed likewise within. There are, however, strong reasons for believing that such may be the case.

Substances capable of putrefaction are present in the digestive canal. Of such, the most common in children is milk, but in neither adults nor children can any article of food be assumed to be absent. In many cases, beside food, there will be mucus, serous exudation from inflammatory surfaces, blood, pus and sloughs.

The micro-organisms which accompany and are believed to cause putrefaction, exist in the digestive tract. Johnston, in the examination of the vomitus of seventeen breast-fed infants affected with summer diarrhœa, found invariably micrococci and what is known as bacterium termo. He discovered in diarrhœal fæces innumerable bacteria, especially of the two varieties mentioned. Since the digestive canal is not free from bacteria in health, it must be inferred that while the digestive function is normal, certain conditions exist by which organisms are held in subordination. Spallanzani found that when substances, in which putrefaction had already begun, were introduced into a living stomach, the process was checked. It may be supposed that in order to initiate fermentative changes, organisms enter the body in uncontrollable numbers, or that digestion is in whole or in part suspended.

The products of fermentation are found. With the sour vomitus and the acrid or foul stools of summer diarrhœa, all are familiar. The search for alkaloids in diarrhœal excrement has probably not been made, but such have been found in healthy fæces, and that freshly-voided fæces are poisonous has been proved by Bouchard. It is probable that the amount of poisonous alkaloids formed in disease is greater than in health, and also that their quantity and the conditions under which they are produced render them less subject to the eliminative action of the body.

What is known of ptomaïnes throws light upon certain obscure conditions arising in summer diarrhœa. There are cases of cholera infantum in which violent symptoms are followed by speedy death, and yet no appearances adequate to explain the result are revealed by the autopsy. There are also cases of diarrhœa, some acute, others subacute, which a few hours before death show, with the condition called hydrencephaloid, a rise of temperature. The nervous symptoms may be referred to exhaustion. It is difficult, however, to explain the increase of temperature by either exhaustion or a new inflammatory process begun in those last few hours of life. It seems more reasonable to believe that, both in this case and the former, a septicæmia has been induced by the products of putrefaction, either absorbed from the digestive canal, or generated in the exhausted tissues of the body.

It is easily remarked that in no case of summer diarrhœa do the symptoms correspond completely with those following the administration of a given ptomaïne to an animal. Of this, an explanation is offered by the fact that a single ptomaïne could hardly exist alone in the digestive canal, since both the albumenoids and organisms present are various. Moreover, different ptomaïnes, though they may have similar, may possess antagonistic powers so that the effect of any one may be modified or even neutralized. It is, therefore, impossible to predict with exactness from experiments outside the human body, what the action of the alkaloids of putrefaction would be when formed within the body.

Many of the expedients which have been found useful in the treatment of summer diarrhœa possess some element unfavorable to the growth of micro-organisms.

The removal of a child from the city to the country or seashore is, in high degree, an antiseptic measure. Investigation of the bacterial contents of the air and earth show that organisms diminish in number as we rise above the surface of the earth, as we penetrate beneath it, and as we go out upon the sea. They are absent in the high Alps, absent or very scarce in the lower strata of the soil, and absent, so far as investigation has gone, in the sea air a thousand miles from land. In the Rue de Rivoli, on the contrary, in the centre of Paris, there are ten times as many microbes in the air, as at the fortifications outside the city; and at Montsouris observatory the north winds blowing over Paris bring many more bacteria than the south winds from the country. The most impure come from the hills of Villette and Belleville, populous quarters, in which also are cemeteries and slaughter-houses. In other words, where there is decomposing organic material, there are bacteria, and the greater the amount of the one, the larger the number of the other. What is true of air is in a higher degree true of water. Condensed aqueous vapor has been found to contain 900 bacteria to the litre, sewer-water from Clichy contains 80,000,000 to the litre. It is where human beings are crowded together in large numbers that the greatest consumption and excretion of organic matter takes place. It is here, therefore, that the widest necessity exists for those retrograde changes which it is the

peculiar province of fermentative organisms to effect. We are justified, therefore, in looking upon filth and sewage as the grand culture medium of fermentative organisms, the special soil in which flourishes the most formidable cause of summer diarrhœa. Removal from this contaminated environment would, therefore, be demanded by theory, and is approved by practice.

It can readily be seen, however, that the advantage which extra-urban residence naturally possesses can be nullified for any particular place by unhygienic local conditions. The insufficient drainage of a country town, the cesspool under the window of an isolated farmhouse, create the same danger which is to be encountered in the midst of a dense population. It is in all cases the proximity of decomposing organic material which is to be avoided.

The transference of a child from the bottle to the breast is an antiseptic measure. Milk, as it comes from the breast, is free from organisms, and human milk, even when allowed to stand exposed to the air, is said by Baginsky to resist fermentation a number of hours longer than cow's milk.

The heating or boiling of milk is an antiseptic procedure. The ancients used to quench flints in milk to render it more suitable for diarrhœal patients. Household observation has taught that "boiled milk keeps." The more exact studies of the laboratory have shown that micro-organisms can be killed by sufficient boiling, and that a fluid thus sterilized will remain unchanged until bacteria are again admitted. To employ completely sterilized milk for infant feeding is hardly compatible with the conditions of a nursery. An approach to this can, however, be effected by boiling milk in the same bottle from which it is afterward to be nursed. The bottle should be stoppered with cotton before boiling, and the stopper removed only when the milk is required for use. Milk, thus prepared, will keep sweet in a warm room for twenty-four hours, while unboiled milk standing in a pitcher by its side, will, in that time, have become sour and coagulated. To thus defer for a few hours the capability of milk to ferment, may be all that is necessary in the treatment of some of the minor cases of vomiting and diarrhœa in infants.

All means for emptying the digestive tract either by withholding food or by giving evacuants have an antiseptic value. On the one hand, micro-organisms are deprived of the material necessary for their growth; on the other hand, both organisms and their products are swept away. Evacuants have from an early period been held in favor in the treatment of diarrhœa. The Greek physicians prescribed mild laxatives to remove the "peccant humors," and Piso, who introduced the use of ipecac for its emetic and cathartic effect in the fluxes, described it, in his extravagant language, as "a sacred anchor and most exquisite gift of nature."

Various drugs have been used to produce disinfection of the digestive tract. To determine the comparative efficiency of these in the treatment of summer diarrhœa does not at present seem possible. It would appear that the value of a particular drug does not depend upon the precise grade of its antiseptic power. A milder antiseptic may, all things considered, be more valuable than a stronger. Nor does it seem probable that complete antisepsis of the digestive tract by drugs is as a rule necessary. The fact that the ordinary processes of digestion are conducted in the presence of bacteria, leads us to think that nature in health exerts a control over micro-organisms. It is probable that she can do something for herself in most cases of disease. The part of medicine, therefore, is so to modify unfavorable conditions as to restore to nature the control which she has lost.

The main positions advocated in this study of summer diarrhœa are:

(1) That micro-organisms bear an important causal relation to a large proportion of cases of summer diarrhœa.

(2) That antisepsis of the digestive tract is an essential element in the treatment of the disease.

(3) That antisepsis should include not only the use of drugs, but the establishment of all conditions known to be unfavorable to the life or activity of micro-organisms.

(4) That, in order to a more scientific use of antisepsis, we require more adequate information as to what organisms are concerned in the production of fermentation, their life history, and the condition favorable and unfavorable to their growth.

REMARKS ABOUT THE DRUM MEMBRANE, WITH CASES.[1]

BY E. D. SPEAR, M.D., OF BOSTON.

What I shall talk about to-night will seem of trifling importance to those in our profession who are bearing the heat and burden of the day and to whom the work of a specialist oftentimes seems to savor of arrogance as he attempts to show his brother practitioner the vast importance which particular organs in which *he* is interested hold in the economy of life.

I therefore begin by presuming that I shall be pardoned for bringing little matters to the attention of great observers.

As a reason for presenting so worn a theme as that of the drum membrane of the ear, I would say that I wish to refer to popular impressions regarding it as a factor in the production of hearing. Every one knows the belief respecting it in the minds of the many. If once injured, broken or lost it is believed that the sense of audition departs. This fallacy is held in the minds of the very intelligent.

Of late writers begin to claim that, on the contrary, this membrane merely serves a physiological purpose of protecting the more deeply lying parts of the auditory apparatus, and consider its presence unessential to hearing! The arguments adduced to prove its functions, or rather to deny its usefulness, are supported by observations made upon that organ in its abnormal condition.

A study of the wonderfully delicate adjustments of which the normal membrane is capable, as shown so carefully by one in our midst, should lead us to respect its presence and urge us on all proper occasions to remove causes tending to prevent its full action.

I proceed to show, by a few cases, that inference as to functions drawn from observations made upon such an organ as the ear in a diseased state may with good reason be acted upon in pathological cases similarly affected, though I believe that the practice of following a routine plan in any class of cases should be avoided as likely to prevent the discovery of new methods.

[1] Read at the meeting of the Boston Society for Medical Observation, March 7, 1887.

In our discussion we may formulate these two inquiries.

First. Given a case of partially destroyed membrana, shall we try to close up the perforation?

Second. A case of intact but greatly thickened membrana shall we *try* to establish a permanent opening?

Two classes of cases claim our notice. Injuries to the drum membrane, of an acute character (perforations or ruptures).

Old perforations; the result of disease.

In the traumatic cases we find: previously unaffected or normal and previously diseased and therefore abnormal membranes.

Representing the first subdivision of traumatic affections is the not uncommon case of, A. B., adult, young woman. Was playfully cuffed upon ear by open hand of a friend who had approached her unawares. Felt concussion of air, heard short sharp report followed by a ringing sound. Felt dizzy; afterwards aware of slight deafness. Membrane is found healthy but with small linear rupture in posterior superior quadrant covered over with a fresh coagulum. Treatment, a placebo. On third day firm union of wound, noise gone and hearing nearly normal. Later perfect hearing.

The comparative rarity of similar cases among the large number of persons who receive blows upon the ear, is accounted for by absence of the favoring circumstances, not because of the infrequence of such accidents. In most cases where the blow falls over the meatus and one would expect a ruptured membrane "forewarned is ably forearmed" for the expectant musculus tensor and stapedius for that matter prepare the ear for the shock. Experience with simple cases like the above allows one to take slight notice of them and to trust entirely to the natural reparative processes so very active in healthy membranæ. With such cases the answer to question one is easy.

The following cases, however, show the need of remembering that a ruptured membrane may also include injuries to the deeper structures of the ear. I am here reminded, in passing, that it used to be considered almost positive evidence of the very serious injury, fracture at base of skull, if bloody fluid was seen issuing from an auditory meatus.

A young man, attached to a light artillery company, had been engaged one afternoon in firing salutes. He had escaped injury to his ears by taking the precaution observed by the gunners, who present their faces to the concussion wave and by so doing divide it and lessen the shock. If the line of direction is properly judged and the correct position maintained, a blow, which by striking directly might rupture any membrane, is thus parried and normal ears escape injury. As the last round, the twenty-seventh as it happened, was fired, this gunner felt a shock in his left ear, which became deprived of hearing. When examined the next morning a small linear rupture was found very near the centre of a greatly depressed and opaque membrana. Absolute suspension of hearing was proven by appropriate tests.

Patient had for four months been conscious of having slight tinnitus, "a buzzing," in left ear. This had greatly increased. No vertigo complained of. It was decided that the shocks had impacted the foot-plate of the stapes in the oval window, and by compression had abolished the function of the labyrinth. The immediate restoration of fair hearing by the use of the Eustachian catheter confirmed this diagnosis. A watch was heard at 30 centimeters. In this case there was evidence of a more or less chronic catarrh of the naso-pharynx and tympanum, and an explanation for so serious an injury to one ear without disturbance of the other, was easily found. The diseased organ, perhaps because of the infiltration of its protecting muscles, though more likely simply because of the disturbance of its mechanism could not withstand the shock.

This remark has an important bearing upon those cases whose type is found among those exposed to loud noises, and in whom the prominent symptom is a high grade of deafness. A few aurists have called this form "boiler-maker's deafness" which would imply a disease peculiar to ears exposed to a constant succession of loud shocks. My observations upon all such cases have shown an accompanying long-standing disease of the tympanum, usually chronic catarrh, and the condition of the sound-conducting apparatus here found explained why the labyrinth should suffer. If loud noises cause deafness then one ought always to find those employed at noisy trades deaf.

I once asked the manager of a stamp-mill if his workmen were not all deaf. He replied "no! I have twenty-one crushing machines in one room and the men who work nearest the noisest of them can hear perfectly. Only those workmen who have catarrh are affected by the noise."

Another case, illustrating the weakness of diseased membranes, was that of C, a young man who applied for relief of deafness "of a week's duration," which he claimed followed immediately the receipt of a blow from the open hand of a companion with whom he was having a friendly bout. Here was found a large, irregularly oval opening through a very delicate cicatricial membrana. A look at his other ear revealed a membrane likewise delicate, though bearing large patches of calcareous matter. In this case the inference, therefore, was that the suddenly occurring deafness was to be explained on the probability that at the time the injury was received the man's hearing power was far below the average, the result of a former disease of both tympana and that the slight additional loss was noticed because of this fact.

The contrast in the very large perforation without coagula to that of the small linear rupture of a normal membrane clearly showed how delicate had been the reproduced membrane which is always composed of two layers only, a mucous and dermoid, lacking the fibrous middle layer.

Treatment of this case by paper or cotton discs would have been out of the question. The certainty of destroying more tissue by pressure as well as the impossibility of re-establishing a reparative process in the edges of such a structure prevented the trial.

Of ten successive cases of traumatic rupture noted within a short period, seven gave evidence of previous disease in the ear, one of the remaining cases was that of double rupture with history of free hæmorrhage and consequent purulent discharge from exposure to shock of a dynamite explosion.

The question of closing old perforations can be decided by reference to the special case under consideration. A choice of methods, too, remains.

A small opening in an otherwise healthy membrane

should be closed always, provided if the artificial membrane improves the hearing; because, without this, the risks to be incurred from its use would more than counterbalance its possible good effects. I found, in a boy of fourteen, total destruction of the membrane with adhesions about the stapes, in one ear, no hearing. In the other, a large oval perforation at the centre below the malleus. A paper disc over this latter opening so improved the hearing that treatment was decided upon. The paper was applied at intervals sometimes completely closing in the opening, at other times only partially covering it until irritation was caused, when it was removed and the ear left to recover. In one instance, after having been left on four days, congestion of the whole tympanic mucosa followed, and serum filled the tympanum. This attack, unattended with pain, indeed, unnoticed by the patient, with other slight relapses brought about absorption of material previously thrown out, possibly around the articulations of the ossicles and by allowing freer movements, improved the hearing to a point reached by the ear with its membrane as at first restored to its entirety. Future treatment of the case, it is hoped, will bring further improvement.

In the case which follows, a small perforation in a diseased (partially calcified) membrane is allowed to remain open because the hearing power is apparently nearly up to the normal standard and when closed by a paper patch, this is perceptibly diminished.

Observations upon the growth of the outer layer of the normal drum membrane having shown [2] that this tissue is constantly replaced by the reproduction of cells as on the skin, but that the tendency of their growth is outwards, starting from points on the membrane at or near its centre, towards the periphery, and posteriorly along the wall of the auditory canal.

This was clearly shown by the application of delicate paper discs to the surface of the membrane, which in course of time, were found to have changed their position with relation to fixed points. The rapidity of this movement and its general direction being determined by their relative proximity to the central part of the membrane and by their position in front of or behind the mamebrium mallei. The discs placed posteriorly moved most rapidly and in the straightest lines, whilst those anteriorly were obliged to take a longer route and were even retarded by the slower growth of the epithelium in this situation. It was observed further that there was a spiral line taken by a disc placed above and in front of the tip of the malleus, by which the posterior periphery of the membrane was reached instead of the anterior.

Experience with paper patches upon the membrane, over perforations, also shows this tendency to displacement so constantly, that in practice it is necessary to readjust the "artificial membrane" periodically, to insure its therapeutic action: permanent closure of the perforation and improvement of the hearing.

By way of further illustrating this subject and with a view of giving additional evidence upon it, the citation of this case is presented.

L. F., adult, placed herself under my care for the relief of deafness accompanied with tinnitus. For six months patient had noticed a discharge from the right ear which within two months previous to her first visit had stopped, when the left ear began to take on the same condition.

Her ability to hear ordinary conversation was much impaired, and the watch was heard only after contact with the auricle. Upon inspection the right tympanum was found full of fluid without an opening through the membrane. Upon the left side otitis media with sero-purulent discharge through a small perforation in front of and just below the tip of the malleus.

The treatment of the right ear may form the subject of another paper. That of the left resulted in great improvement in hearing and cessation of the discharge, but a perforation remained as above without any active process going on around it. The idea of bringing about the closure of this opening suggested itself, and a bit of "sized foreign note" was accordingly placed in position over it. In attempting to accurately adjust this, my probe unluckily pressed upon one of its edges and caused it to pass into the perforation, where it was only distinguishable by a line of light marking its vertical position. Efforts made with forceps and syringe, failed to replace it and only resulted in pushing it out of sight altogether. The paper was of necessity allowed to remain, and conjectures as to its probable position and future adventures were for many weeks indulged in. As no inconvenience was experienced by the patient then, nor has been since, other than sensations of fulness or heaviness (which were always found to be due to temporary obstruction in the eustachian tube and removed by the air-douche) no interference was necessary. After the lapse of two months time the paper disc was again visible upon the membrane above and close to the perforation. Since this reappearance its progress has been carefully watched and these observations noted. The disc has been covered by epithelium; the line of its advancement has been upwards and a little forwards, and at this writing, six months from the date of its first application, the extent of its journey has been reached, and it has left the membrane near its periphery, just under the anterior fold by a process of detachment brought about by the pressure of underlying layers of epithelium as they have accumulated from time to time. The foreign body was at first upon the inner surface of the membrane to the front of the perforation. It was very slowly brought through the perforation and took up a line of travel anteriorly and upwards. In was observed in Blake's experiments that a disc of paper placed upon a membrane at a spot corresponding to the perforation, in one case travelled downwards and posteriorly. Why did not this also? Plainly because the disc became placed upon the upper edge of the opening in the membrane where the direction of growth was upwards out of reach of those cells moving in the opposite direction (on the further side of the perforation). Further, Blake speaks of a "period of hesitation," at this part of the membrane. Undoubtedly, the dividing line between the two extremes of motion lies just at the tip of the malleus, as these observations would show, and the cause of the hesitation is explained by his having put his disc very near this dividing line where antagonizing forces may be supposed to have been acting. Another interesting question is, why was so much time consumed before the periphery of the membrane was reached? For the reason that its progress was retarded by friction against the edges of the opening, as well as by the

[2] American Journal of Otology, Oct., 1882. "The progressive growth of the dermoid layer of the normal membrana tympani. C. J. Blake, M.D."

fact that from this very retardation the epidermal coating had grown over the paper and could therefore act upon it only against the frictional resistance of its under surface. Again, because it moved slowly and was therefore being lifted off the membrane, it steadily got further and further from where the most active growth was going on, and received in consequence less and less of its momentum. The practical bearing which these facts seemed to have, suggested the idea that an artificial opening in a membrane intended to bring improvement in hearing by allowing sound waves to fall directly upon the stapes, should be made in front of the umbo of the malleus and would remain open for a longer period of time than those made in the usual positions. All my attempts to carry this theory into practice failed, because the nearness of the promontorium to the membrane prevented the knife from cutting. I have on this account considered the feasibility of using an instrument constructed like the ordinary pneumatic speculum but having a paracentesis knife so connected with it as to permit of a cut being made in the membrane while it is drawn outwards.

This leads to the consideration of our second inquiry; should attempts be made to establish an opening through the membrana?

Much has been written and said upon this subject since the beginning of this century and, notwithstanding the many failures, every aurist desires to find the way. Some have been very heroic in their experiments, and have in their eagerness to succeed greatly overdone the matter.

My slight experience has taught the futility of all such designs, and though some few cases are benefited by the trials, the improvement is to be attributed to the absorption of the products of former inflammations occasioned by the irritation, rather than to the immediate results of the operation itself.

REPORT ON OBSTETRICS.

BY CHARLES M. GREEN, M.D.

EXCESSIVE VOMITING OF PREGNANCY.

AT a meeting of the Gynæcological Society of Dresden, November 4, 1886, CHAZAN [1] reported two interesting cases of this affection. In the first case the pregnant uterus was found to be retroflexed: after correction of the displacement and the introduction of a suitable retaining pessary, vomiting entirely ceased and the pregnancy continued without further disturbance. In the second case, that of a woman pregnant for the fourth time, who suffered from continual vomiting from the third month, no anomaly could be found in the pelvic organs by repeated examinations: it was learned, however, that the woman was inconsolable at the idea of being pregnant and wished to be rid of the product of conception. Vomiting continued many days several times an hour; but if the attention of the patient was entirely diverted by conversation, vomiting ceased for an hour or two and then returned. After the patient had been treated with various drugs for some time without effect, she was again carefully examined under anæsthesia. After this the vomiting suddenly ceased and did not return; apparently, as was learned, because the patient believed that while under the influence of the anæsthetic the fœtus had been removed. On the strength of this case, Chazan expressed the opinion that perhaps in most cases hyperemesis gravidarum was attributable to some affection of the nervous system or of the mind, and not to a genital abnormality, as some authors believe: and in support of his opinion he mentioned the frequent occurrence of excessive vomiting without coincident affection of the genital organs; the comparative rarity of hyperemesis in spite of frequent genital anomalies in pregnant women; the more frequent occurrence of the affection in the better classes; the sudden invasion after some psychical disturbance, and the immediate cessation after mental diversion.

In the discussion which followed Chazan's communication, but little support was accorded to its sweeping generalization, although neurotic and psychic causes were acknowledged to be factors in some cases. LEOPOLD spoke very clearly, and divided the cases of excessive vomiting into three classes:

(1) Those in which there is a displacement of the uterus, especially retroflexion. In these cases the vomiting depends on the excessive stretching of nerves and of the uterine muscle.

(2) Those cases in which only affections of the stomach appear to give rise to excessive vomiting.

(3) The cases in persons of neurotic temperament, wherein no anatomical changes are demonstrable.

LEOPOLD says truly that in each case the cause of the vomiting must be carefully sought for, and that sometimes more than one cause may be operative in a given case. He speaks highly of Credé's prescription, — the administration every five minutes of teaspoonful doses of nourishment, preferably iced milk, the patient lying absolutely quiet and taking the nourishment through a glass tube.

Cocaine is highly spoken of by many observers. BOIS [2] relates the case of a young woman in her third pregnancy, who suffered with gastric disturbances to such a degree that she could take no nourishment whatever. Cocaine, opium, and other drugs, given internally, had no remedial effect. The condition was so serious that abortion was about to be performed when Bois determined to try the effect of local treatment of the uterus. He had made a salve after Beaumetz's formula — cocaine 1.0, vaseline 50.0 — and with this he smeared a tampon and placed it against the cervix, leaving it *in situ* for an hour or two: this was repeated twice a day for three weeks. Gradually the patient improved, took and digested nourishment, and was finally cured.

A NEW EXPLANATION OF RENAL TROUBLES, ECLAMPSIA, AND OTHER PATHOLOGICAL PHENOMENA OF PREGNANCY AND LABOR.

A. F. A. KING (Washington) has written a long paper [3] on this subject and advanced a new theory of the renal affections of pregnancy. The paper does not admit of sufficient condensation to warrant its reproduction in this report by abstract; but all who are interested in the subject will do well to read the article in detail. Briefly stated, the author's theory is that "disturb ances in the renal circulation and renal functions are produced chiefly by pressure of the gravid uterus upon the abdominal aorta or its branches, or upon the vena cava or its branches, or upon both or all of these, in

[1] Centralblatt für Gynäkologie, 1887, No. 2.

[2] Bull. Génér. de Thérapeutique, 1886, No. 11. Centralbl. für Gynäk., 1886, No. 51.

[3] American Journal of Obstetrics, 1887, Nos. 3 and 4.

consequence of the child and womb not maintaining during pregnancy their normal lateral obliquity above the pelvic brim." The author submits that the normal position of the uterus before the advent of labor is the lateral oblique position, and that "the normal presentation and position of the fœtus in utero during pregnancy, before labor begins, is the dorso-anterior position of an oblique presentation." He also declares that the normal position of child and womb is "intrinsically the same in primiparæ as in multiparæ," and that it is abnormal for the fœtal head in primiparæ to enter the pelvis before the advent of labor. Dr. King then proceeds to show that "when the normal obliquity of womb and child is maintained during pregnancy, there will be no injurious compression upon any bloodvessels."

The author's theory is ingenious and is modestly presented: he admits that his views are theoretical and only hopes that they may stimulate research which will verify or disprove them. While many will not now accept his premises, those who have large clinical facilities will do well to examine them with care and give them that clinical test which alone will determine their value.

HÆMATOMA OF THE EXTERNAL GENITALS AND VAGINA.

LWOFF [4] has written on this subject, and reported five cases observed by him, which formed during or soon after labor. Regarding the ætiology of these blood-tumors, he concludes that neither the age, the number of the pregnancy, nor the length of labor are in themselves alone causes of the tumor formation; but rather varicose dilatations of the veins in the external genitals, congenital hæmophilia, and congenital anatomo-histological changes in the vessel-walls whereby the latter become more friable: changes in the structure and nourishment of the vessel-walls during labor are also predisposing factors.

The results of these tumors Lwoff groups under five heads:

(1) Death from hæmorrhage with or without opening of the hæmatoma;

(2) Death from septic infection through purulent degeneration of the tumor-contents, chiefly after the opening of the sac;

(3) Opening of the tumor and healing;

(4) Opening with subsequent formation of fistulous communications from the vagina to the perinæum or into the rectum, and protracted healing;

(5) Absorption of effusion without opening.

In the way of prophylactic treatment little can be done, except to hasten the second stage of labor in cases complicated with genital varices and especially in those affected with the hæmorrhagic diathesis. During the formation of the tumor one can perhaps restrict its increase by pressure and cold in the form of an ice-bag or by means of a colpeurynter filled with iced-water. One should avoid opening the tumor as long as possible: if, however, the sac must be opened during labor or soon after, or if it bursts spontaneously, a tampon must be carefully packed into the cavity, both for the purpose of stopping hæmorrhage by pressure and to prevent a refilling of the sac. The author discards the sesquichloride of iron, since on account of the formation of loose, fragile clots the danger of a secondary hæmorrhage is very great, and prefers to tampon the cavity with cotton wads soaked in iodoform and glycerine. If the effused blood breaks down, the cavity should be washed out several times a day with a 1 in 2,000 solution of corrosive sublimate and then dusted with iodoform. If for any reason the sac must be laid open, the result is the more favorable the later incision is performed. [This can hardly be true when there is evidence of beginning disintegration of the clot. REP.]

PROGRESS IN CÆSAREAN SECTION.

Reports from different sources of the continued and increasing success of the new Cæsarean operations are very gratifying to those who confidently expect these operations to ultimately displace in most instances the performance of craniotomy.

In the *Archiv für Gynäkologie*, xxviii, 1, are reports of twelve successful cases by different operators.[5] WEISS (Schwerin) performed the Porro operation in a iv-gravida with a simple flat pelvis, whose previous labors had been difficult and instrumental (once craniotomy), and followed by a protracted and febrile puerperium. In the fourth labor the vagina was found to be so contracted with cicatrices that in spite of strong pains the cicatricial ring would admit only the index finger and there was imminent danger of rupture of the uterus. Weiss chose the Porro operation in preference to Sänger's, because the patient had already had a chill and was feverish, and because in view of the vaginal contraction he thought it wise to prevent the recurrence of pregnancy. The child was saved and the patient left her bed on the twenty-first day.

LEOPOLD (Dresden) reports five cases performed after Sänger's method and three after Porro's, in all of which mother and child were saved. The Porro operation was elected in two cases on account of cancer of the cervix, and once because of extreme pelvic contraction and an inflammatory condition of the uterus due to long labor. The Porro cases had a normal convalescence, but required from four to six weeks after the separation of the stump for the funnel-shaped depression in the abdomen to heal completely; whereas, in the Sänger cases, convalescence was more rapid, and patients left their beds after fourteen days.

CREDÉ (Leipsic) reports two cases after Sänger's method, in both instances on account of a flat, rachitic pelvis. Both mothers convalesced normally, and both children were saved. Credé resected the muscular tissue in both cases, folded in the peritoneal coat and closed the incision with both deep and superficial sutures,— the former of silver, the latter of silk.

SKUTSCH (Jena), who also reports a successful case, says that if there is no especial need of haste it is better to delay the operation until the pains have dilated the cervix, in order to ensure a free exit for the lochia. If, however, the operation is necessarily performed before the cervix is dilated, a drainage-tube should be passed through the os and lochial retention thus prevented.

In the same *Archiv*, xxx, 2, the latest issue, Credé reports his seventh successful Sänger operation, and gives a table furnished him by Sänger embracing all the reported cases after this method from May 25, 1882, to April 15, 1887, fifty in number. Of these fifty cases 72 per cent. of the mothers and 92 per cent. of the children were saved. Thirty-four of the cases

[5] Centralbl. für Gynäkol., 1887, No. 20.

cases were German, and of these 88 per cent. of the mothers recovered and 94 per cent. of the children were delivered alive. The fourteen Dresden cases resulted in thirteen maternal recoveries and fourteen living children. In the seven Leipsic cases, the mothers and children were all saved.

It will be seen, therefore, that the mortality of the improved Cæsarean section, as an elective operation in the hands of experienced operators, is lower than that of craniotomy; and it is not an unreasonable expectation that with the increasing consideration for fœtal life, the modern conservative methods will in all enlightened communities displace, in most instances, the destructive operations.

Clinical Memorandum.

TYPHOID FEVER WITH UNUSUAL FEATURES.[1]

BY F. E. PORTER, M.D., AUBURNDALE, MASS.

IN August of 1885, I was called to a store to see a man who said he had taken cold during the rain of the week previous; had headache, back and legs ached off and on ever since; nose bled the morning before, face anxious and pale, eyes seemed prominent and larger than usual. Patient thought he had indigestion, and had for a few weeks back resorted to an apothecary for plain soda, which seemed to him to help him. Some rolling and tumbling in bowels, though no diarrhœa, tympanites or sensitiveness to deep pressure in iliac fossæ. Surface dry, pulse 116, temperature 101°, respiration 32.

Advised him to at once go home, take warm bath, apply warm pack to abdomen, and drink, in the course of a couple of hours, a tumbler of water containing

℞ Liq. Ammon. Acet. . . . . ʒi.
Syr. Limonis . . . . . ʒi. M.

and if sleepless and restless at bed hour take gr. vi Dovers' powder. The next morning he told me he slept well, sweat freely, and felt better. Pulse 94, temperature 103°. At 5 P. M., pulse 100, temperature 104.4°; advised spongings with soda water, and Dover's powders gr. iv. at bed hour, if necessary. On second morning his pulse was 100, temperature 102.8°, respiration 24, bowels had not moved, though often threatened to; tongue brownish coat on sides; tip clean; said he "dreamed last night, and sweat in his sleep." 5.30 P.M., pulse 88, temperature 104.3°, nervous and restless, bowels uneasy.

No discernible change took place until the fifth morning. Pulse was then 92, temperature 102.6°; his friends said he was wandering during the night, and often required a strong man to keep him in bed. Up to this time he had been fed with plain, liquid, nutritious, and in part concentrated nourishment. At 2 P.M. was suddenly called, the patient having thrown himself in delirium about the bed, and could not be held. While there noticed his heart was fast failing, weakened action, frequent stops, irregular, surface growing cold, capillary circulation poor, nails blue, mouth wide open, and gasping respiration. Heaters, hot packs, hot coffee, hot water and brandy, and constant attention alone succeeded in whipping up the heart to renewed action and work.

7 P.M. Violent, and many men had to hold him; eyes bright and glistening, pupils dilated, saying nothing, but eyeing, hearing, and knowing all, refusing everything. Pulse 140, temperature 102°, respiration 36; strength and power unnaturally increased, throwing men away from him in different directions. Consultation was sought with several physicians, and late in evening Dr. Thayer arrived. While rehearsing the condition in adjoining room, was suddenly called, to find patient wrestling with five men. Codeia, in grain doses, an hour apart was advised. At 2 A.M., after about five hours of extreme exertion, which of itself would inevitably wear out the patient in short time, and being unable to administer ether, which in many directions seemed preferable, I gave one-half grain of morphia subcutaneously; then waiting forty-five minutes for results without finding any, three-eighths more was injected. In fifteen to twenty minutes his exertions began to cease, and a controversial tack set in. At 4.30 A.M., he was asleep, which continued until 9.30 o'clock on the sixth morning. Pulse, temperature, respiration, state of surface, pupils, etc., corresponded to action of morphia in the system. During sleep patient sweat like rain, as indeed he had for past three nights. When he awoke, his mind was perfectly clear, called for milk, toast water, clear water, beef-tea; bowels moved and bladder emptied voluntarily, and the patient commenced to advise about pulling together in pulling him through, though soon after declared to those about him, he could not get well, "was all broke up," declared he must die, at the farthest in a few hours. Large discolored spots were now discovered about his hands, arms, thighs, and knees, one or two about the trunk, with here and there an abrasion, notably over the joints. Petechiac, usually found about the chest and abdomen, were not seen. Another failing of heart's action set in with its attendant symptoms, which were promptly met with hypodermics of brandy, etc.

At 2 P.M., he was fast becoming delirious, and seemed maniacal. Had he the strength of the preceding twenty-four hours, I have no doubt the same fight would have to be repeated. A hypodermic injection of one-quarter grain of morphia sulphate stopped the muscular exertions, though the time was occupied with much talking and occasional sleep. At nearly midnight I left him, with pulse 145, temperature 100°, respiration 45, with directions to have brom. potass., sodium, et ammonium, and chloral hydrate aa. gr. x, in a suitable menstruum given per rectum, should raving again set in. Having a professional man nurse on hand at that time I could rely on the execution of orders. He continued to fail during the night, and at 6 A.M., on the seventh morning of attendance, was called to find the pulse had been failing at the wrist for an hour, and now gone, heart's action 125, respiration sighing, and patient moribund. At seven o'clock all was over.

At 9.30 o'clock the undertaker found me and said my patient was fast growing unrecognizable, parts soft and dusky, abdomen swelling, ecchymotic spots, the size of a dollar to size of hand, appearing on back and legs. I saw him at ten o'clock and again at 2 P.M., when he was beyond recognition.

Extremities were fast amputating themselves,[2] and

[1] Read before the Middlesex South District Medical Society.

[2] In confirmation of the above, the undertaker tells me he was obliged to lift the body on a sheet in putting it into a hermetically sealed casket. At the funeral, while carrying the remains into and out of the church, the pall-bearers said that different ends of the coffin were heaviest, according as it tipped during conveyance, and sounds were heard as of fluid in motion while the casket was in their possession.

I told the friends that he died at the point of saturation with the poison; a gross statement to be sure, but one I thought more readily acceptable to them than any more refined elaboration of the condition.

Two or three reflections occur to me as I review this case. One is, the falling of the temperature when the cerebral irritation became pronounced. In this connection I will quote Liebermeister. "A condition of special interest, which sometimes develops itself at the height of the disease has been called by me, irritation of the brain with depression of temperature. Sometimes, about the middle of the second week, at the height of the disease, in a patient who has had continually high temperature and the corresponding functional disturbances of the brain, the brain symptoms suddenly assume an anomalous character; they become such as to suggest meningitis; or well-marked mental disturbances appear, either partaking of the character of melancholia or with maniacal tendencies, the pupils at the same time losing their sensitiveness to light.

"The striking feature of this condition, however, is that the temperature of the body, which has thus far run its ordinary course, and has for the past few days remained at about 104° F., or over, suddenly falls, when the evidences of irritation of the brain appear, and, during the continuance of the brain symptoms, fluctuates in an irregular manner between 98.5° and 100.5° F., or even between 97° and 102°.

"In favorable cases the brain trouble disappears in a few days, or it may not be until a few weeks have elapsed, and then the temperature rises again to a point corresponding to the stage of the disease, and the regular order of things is resumed. . . . It is a condition most apt to supervene in grave cases, and the irritation of the brain appears to result from the influence of a high temperature on that organ. The lowering of temperature which exists during the continuance of irritation of the brain may, perhaps, be most easily explained on the supposition that the controlling nerve centre, which presides over the regulation of temperature, is itself involved in this irritation."[3]

Another reflection is, the early appearance and desperateness of the nervous symptoms. Murchison says, "As a rule, it does not commence until the middle or end of the second week, and it often does not appear until the end of the third week. . . . Still there are exceptional cases where the delirium occurs earlier. Louis mentions two instances where the patients were delirious during the first night. Jenner observed delirium, occasionally one of the earliest symptoms. Bristowe records a case where maniacal deliriums occurred on the second day." In three cases in which Murchison had been consulted, "the illness had at first been regarded as acute mania, and in two of these cases removal of the patient to a lunatic asylum had been contemplated."[4] Flint says: "Exceptionally it is manifested in the first week, and even when the patient first takes to bed. . . . So far as my observations go, persisting, active or violent delirium, requiring restraint, is an extremely unfavorable symptom."[5]

Lastly, the rapid decomposition after death. In this disease I do not remember ever to have seen such changes recorded. It must imply an unusual amount of the poison received. It is unusual also, to see patients die thus early in the typhoid run. Emaciation is not pronounced, the fluids and fat are not yet reduced. Must it not mean, that the materies morbi is the main factor in this instance; while the fever, an attendant upon the disease, has not as yet more than commenced to work its own destructive processes? I have thought that the excessive muscular exertions, also, were a factor in the rapid destruction. The amount of nerve-power necessary to execute such movements, for so many hours without sleep; the amount of tissue waste of all sorts, with a poisoned nutrition, the blood, hastening to supply the loss of itself, would contribute *de*generation for *re*generation. One writer attributes the early appearance of delirium, not to any degree of fever that the patient as yet has had, but to the typhoid poison *per se*. And, I see nothing in the way of supposing, that a material, introduced into the system in amounts sufficient to so soon beget cerebral delusions, fancies, stimulating and perverting its energies to maniacal proportions, can, when driven throughout the economy at a heart gait of one hundred and forty and upwards, render every kind of structure, save the fibrous and bony, sufficiently pathological as, not only to cause early death, but, in warm weather, speedy decomposition beyond any recognition of the individual.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

MARCH 7, 1887, DR. MCCOLLOM in the chair.

DR. E. D. SPEAR presented a paper,

REMARKS UPON THE DRUM-MEMBRANES, WITH CASES.[1]

DR. C. J. BLAKE spoke very favorably of the use of paper patches in the treatment of perforations, alluding to a case of his own, where the patch disappeared through the hole, subsequently reappearing in the secretion. He favored the use of a long or oval patch.

DR. H. L. MORSE said that he had also passed a patch through a perforation, and in no way had he since known what became of it. At all events, it had produced no bad symptoms. He spoke, also, of the common fallacy of thinking that a perforation must necessarily induce deafness. In a case that he had had under treatment, where injury had been caused by the use of a fountain-syringe in removing plugs of cerumen, he had derived great advantage from the use of Politzer plugs, when other means of restoring the stapes to its normal position had failed.

DR. F. L. JACK reported some cases illustrative of the fair amount of hearing possible, despite large perforations.

DR. LELAND alluded to the employment, of the inside skin of the egg-shell, instead of paper, as having produced better results in his practice. In one case, it was worn without renewal for two months.

— It is said that a tooth immersed in a solution of the tincture of iron in eight parts of water, has its enamel entirely destroyed in one hour.

[1] See page 177 of this number of the Journal.

AMERICAN OPHTHALMOLOGICAL SOCIETY.[1]

TWENTY-THIRD ANNUAL MEETING.

CASE OF CONGENITAL ZONULA GRAYISH-WHITE OPACITY AROUND THE FOVEA,

by O. F. WADSWORTH, M.D., Boston.

The patient was a child eleven months of age. She was unable to sit or stand and could not hold anything in her hands. She appeared to take little notice of anything. Externally the eyes were normal. With the ophthalmoscope the disks did not seem to vary from the normal appearance. The macula was dark red and surrounded by a grayish-white opacity. The remainder of the fundus appeared to be normal. There appeared to be some light perception. Five months later there seemed to be no perception of light. The disk was sharply defined; the central vessel small. The mother had had four healthy children. The fifth, according to the history, had been sick in a similar way as the one under consideration. In all the reported cases some weakness of the general muscles was noted.

SEPARATION OF THE RETINA IN BOTH EYES WITH ALBUMINURIA OF PREGNANCY: REPLACEMENT,

by O. F. WADSWORTH, M.D., Boston.

The patient was a married woman, seven and one-half months pregnant. About the beginning of the eighth month œdema of the eyelid appeared. This was soon followed by indistinctness of vision. The urine was loaded with albumen and contained hyaline and granular casts. When seen by the speaker there was a general separation of the retina in the right eye. In the left eye there was also separation of the retina but not so distinct. After consultation, it was decided to induce premature labor. This was done and a living child was delivered. Before the completion of labor a convulsion occurred for which bleeding was resorted to. The patient convalesced and vision gradually returned. When last seen the disks were clearer. No separation could be made out in either eye.

DR. B. ALEXANDER RANDALL, of Philadelphia, read a paper describing

A CASE OF COLOBOMA OF THE OPTIC NERVE.

DR. F. BULLER, of Montreal, Canada, read a paper describing

A PECULIAR FORM OF GRANULAR CONJUNCTIVITIS ASSOCIATED WITH ICHTHYOSIS.

Two cases in which this combination was present were reported.

SECOND DAY. — AFTERNOON SESSION.

DR. W. S. DENNETT, of New York, exhibited an ophthalmoscope, in which the mirror was substituted by an electric light.

DR. LUCIEN HOWE, of Buffalo, presented a small pocket ophthalmoscope, with movable disc.

Dr. Howe also exhibited several photographs of the

INTERIOR OF THE HUMAN EYE.

DR. EDWARD JACKSON, of Philadelphia, presented a

SET OF SMALL TEST-LENSES, WITH A MODIFIED TRIAL FRAME.

The lenses are one inch in diameter, and the saving in weight is from one-third to three-fourths of the weight of those in common use. The lenses are plano-convex and concave, giving advantages over the double convex and concave by lessening spherical aberration, being easier to combine together, and making it possible to neutralize more perfectly spectacle-glasses, the strength of which it is desired to test. Several lenses had been added to the series usually placed in such sets, including stronger concave spherical and two astigmatic lenses, which had been found very convenient in testing for astigmatism. It was suggested that all intermediate lenses added to the metric series should be made to divide in half the present interval of one-fourth dioptry, making the interval one-eighth, and preserving the simplicity of the system.

Making the lenses smaller allows the trial frame to be made smaller, and very much lighter, so that the new frame, with the new lenses, weighs less than half the old frames, with lenses of equal strength. The temple of the frame is attached to the lower part of the lens-holder, allowing the lenses to be placed in the back groove of the holder, or withdrawn therefrom through the natural depression of the temple, instead of across the prominences of the brow or cheek. The set and frames are made by Queen & Co., of Philadelphia.

DR. S. D. RISLEY, of Philadelphia, described an

OPHTHALMOSCOPE WITH CYLINDRICAL LENS.

The ophthalmoscope is of the usual form, but behind the mirror there are two slides, containing the cylindrical glasses. In one slide the cylinders are + .50; 1.00; 1.50; 2.00; 2.50; in the other, + .25; .30; 4.00; 5.00; and 6.00. With these numbers, any desired combination can be made. The axes of the cylinders are rotated by rotating the instrument as a whole. The instrument is especially useful at the bedside for the purpose of correcting a high degree of astigmatism, when present.

A MODIFICATION OF THE REFRACTION OPHTHALMOSCOPE, WITH AN ATTACHMENT FOR USING CYLINDRICAL-LENS GLASSES,

by SWAN M. BURNETT, M.D., of Washington, D. C.

The modifications of the ophthalmoscope which were offered by the speaker consisted, first, in a clip behind the instrument, into which the cylinders in the test case can be inserted. The inclination of the axis is read on a graduation on the back of the mirror. The author had found this arrangement satisfactory in verifying the diagnosis of astigmatism made by other methods, and for examining the fundus of the astigmatic eye, free from its anomalous refraction. Secondly, two superposed discs containing lenses which singly, and by combination, give 47 numbers (22 plus and 25 minus lenses), with a regular interval of 0.5 D up to 10.5 plus and minus. Thirdly, a plane circular mirror, with a concave tilting mirror swung in front of it. The plane mirror does not interfere with the tilting mirror when in use, and when it is desired to use the plane mirror alone, the tilting mirror can be detached from its upper bearing, and swung downwards out of the way on its lower bearing. The instrument is very light, and it is made by Queen & Co., of Philadelphia, and its cost is about $20.00.

TRANSIENT MYOPIA FOLLOWING IRITIS,

by JOHN GREEN, M.D., of St. Louis.

[1] Concluded from page 161.

In 1867, the speaker had been the subject of iritis, involving both eyes. During convalescence, he noticed that the dimness of vision was not wholly due to lack of transparency of the media and that vision was improved by the use of concave glasses. He had occasionally observed in other patients with iritis, that as they recovered, vision was benefited by the use of concave glasses. Last April, the speaker had iritis affecting the left eye. He was then able to compare the one eye with the other and found that the myopia induced by the iritis amounted to 1.50 D. This gradually diminished until it disappeared at the end of four weeks, leaving the normal refraction. He had been unable to find accounts of myopia as a transient symptom, during convalescence from iritis.

DISCUSSION.

DR. O. F. WADSWORTH, of Boston. I can confirm Dr. Green's observations with reference to the occurrence of myopia during the convalescence from iritis. Patients who have had no myopia before, are benefited by concave glasses. This has gradually grown weaker. I have seen this repeatedly, but it does not occur in every case.

DR. G. C. HARLAN, of Philadelphia, reported an interesting case recently under his care.

A young man myopic two and one-half D. came under observation several months ago, with the history that he had spots coming before the right eye, and that there had been a sudden decrease of vision. I found a certain amount of choroidal irritation and a posterior polar opacity. This began as a six-armed cross with rectangular arms. These became more diffused during the following six weeks. During this time, there had occurred a marked opacity in the anterior portion of the lens, without traumatism and with only a moderate degree of choroid inflammation. There was no special increase in the myopia so far as the author was able to determine.

EXECUTIVE SESSION.

The report of the Committee on Congress of American Physicians and Surgeons was received, and the following resolution adopted:

Resolved, That the American Ophthalmological Society appoint a representative, and alternate, to the proposed executive committee of arrangements for the Congress of Special Societies, with the provision that in making the appointment this society does not commit itself to an approval of the present sketch in all its details.

Dr. William F. Norris, of Philadelphia, was elected representative to the executive committee of the Congress, and Dr. D. B. St. John Roosa, of New York, was elected alternate.

The nominating committee reported as follows:

Officers for ensuing year: President, Dr. William F. Norris, of Philadelphia; vice-president, Dr. Hasket Derby, of Boston; secretary and treasurer, Dr. O. F. Wadsworth, of Boston; corresponding secretary, Dr. J. S. Prout, of Brooklyn.

The following were elected to membership: Dr. George Cutter, of Brooklyn; Dr. D. C. Cocks, of New York; Dr. H. S. Oppenheimer, of New York; Dr. Charles McIlvaine, of Trenton; Dr. David P. Beck, of Cincinnati.

The next meeting of the Association will be held at New London, Conn., on the third Wednesday of July, 1888.

AMERICAN NEUROLOGICAL ASSOCIATION.[1]

THIRTEENTH ANNUAL MEETING AT LONG BRANCH.

FRIDAY, JULY 22, 1887.

DR. OTT read a paper on

THERMO-TAXIS.

The speaker called attention to the increased rise of temperature upon nerve-irritation, the effect of atropia upon the nerve-system, and the rise of temperature after the administration of this drug, its maximum effect being produced at the end of two hours. He considered stimulation of the heat-centres was produced by these means. He also called attention to the rise of temperature in cases of tetanus and convulsions.

DR. SPITZKA mentioned two cases of chorea, the temperature, in one case, rising to 104°, and in the other, to 107°. He had no reason to account for that rise of temperature, except the strong muscular action exhibited. He had also seen a case of chorea that resulted fatally, in which the temperature was 103°.

DR. DANA read a paper

ON A CASE OF ANENCEPHALITIS ILLUSTRATING THE SENSORY TRACT.

The case was that of a male child born at full term, weighing eight or nine pounds. There was no deformity, except that the head was rather peculiar, being very long and narrow. The bones were freely movable; the eyes were kept closed. The child died on the second day. At the post-mortem, a yellowish fluid squirted out from the brain. The first nerve was not fully developed. The arterial supply was inferior and undeveloped in some of its branches. The pons varolii was small, as was also the spinal cord. The speaker presented some excellent drawings of sections of the cord and brain, also, of these parts in the normal subject; the smallness of the cord being due to the diminished size of the lateral columns, the anterior columns, also, being narrower than normal. The gray matter of the cord and its cells was fairly developed.

THE TREATMENT OF NEURALGIA BY MEANS OF INTENSE COLD,

by GEORGE W. JACOBY, M.D.

The reader concluded that we possessed two refrigerants, chloride of methyl and the fluid carbonic acid, which can be easily and practically utilized in the treatment of neuralgias.

DR. MILLS asked the reader if he had used rhigolene.

DR. JACOBY replied that he had, but could not obtain the requisite amount of cold. In sciatica, however, it had produced decided relief for a long time, but it requires a great deal of rhigolene. Although it is cheaper, it takes so much that it really makes it expensive.

DR. LLOYD asked what the apparatus used by Dr. Jacoby costs.

DR. JACOBY replied that it cost $37.50, and one cylinder could only be used four times, but in Paris it could be filled for six francs.

DR. CHARLES K. MILLS, of Philadelphia, presented

[1] Concluded from page 161.

NOTES OF SOME CASES OF MULTIPLE NEURITIS (OR MYELITIS) OF SYPHILITIC ORIGIN, WITH REMARKS ON THE DIFFICULTIES OF DIAGNOSTICATING MULTIPLE NEURITIS FROM SOME FORMS OF MYELITIS.

The differential features given by Chapin, Starr, and others he regards as insufficient. Some of them were misleading. Common both to multiple neuritis and myelitis of the forms indicated, were atrophic paralysis, lost knee-jerk, and degeneration reactions, according to the best observers. Pain and tenderness were, in character, distinctly localized to nerve-trunks or certain muscles, and the absence of symptoms of paresis or paralysis of the bladder and bowels seemed to be the most definite marks of multiple neuritis, but could even these be regarded as positive, or, at least, absolute? It was certainly fallacious to decide in favor of neuritis, because of gradual onset, because the cases got well, because the paralysis was progressive and ascending, or because of the presence of numerous and persistent sensory manifestations.

DR. MILLS remarked that when the nerves and central organs were both involved, it was difficult to say which was first involved. He considered there were cases where it was impossible to discover whether the disease was central or peripheral. If we have paralysis of the muscles with loss of sensation and degeneration, the speaker thought it was neuritis; if sensation was present it was probably central.

DR. EDES stated that he reported a case some years ago in which he found symmetrical lesion in the cord; there was the usual amount of asthenia with rapidly advancing paralysis and atrophy below the knees and elbows; the case resulted fatally. The speaker thought Dr. Mills was right, and that these two things may co-exist, but whether the degeneration of the cord was owing to neuritis he would not be certain. He thought the tendency was to call these cases neuritis.

DR. PUTNAM remarked as to the connection of neuritis and the anterior columns of the spinal cord, the pain felt in polio-myelitis is really neuritic in origin. He had seen cases of pain with a loss of sensibility where the cord appeared to be healthy, but where the brain had spots of softening, the arteries were greatly thickened in the central nervous system. As Dr. Mills had suggested, the different types differ so strongly that we have to conclude we are dealing with a system of disease, and that the spinal cord and peripheral portion are related in some way. As regards the knee-jerk being exaggerated, several cases had been reported; the speaker could add two or three cases; he had examined cases of lead-poisoning and had quite a number of cases where the knee-jerk was exaggerated, where the symptoms would have suggested neuritis; this may be part of the general condition of hyperirritability of the nervous system.

DR. MILLS remarked he would like to get a positive opinion as to whether or not the presence of pain along a nerve trunk and hyperæsthesia can be present in the absence of peripheral nerve disease.

DR. LLOYD suggested the use of electricity as a means of diagnosis in these cases.

DR. STARR did not think this means could be depended upon, as the intensity of the disease was so varied. He thought a great many cases of polio-myelitis began without any sensory symptoms at all, and where it does occur at the beginning, the question comes in as to whether it is not neuritis; he did not remember seeing any cases where the cord was affected equally on both sides, one arm would be affected more than the other, and so it would be with the legs. In multiple neuritis both sides were affected similarly; as a rule, cases that he had seen during the past year followed out that idea. The speaker considered it a mistake to consider all cases that recover, neuritis; neuritis is not always favorable in its course, but it is more favorable than the other; there is a form of subacute polio-myelitis which may correspond with neuritis, pain and tenderness being points of great value in diagnosis.

DR. SPITZKA thought the pathological specimens too few to base any definite opinion on. In the last few months he had seen three cases where he would have defied any one to show him that they were cases of acute bulbar paralysis. They were after diphtheria; there was intense neuritis.

DR. DANA remarked that he considered alcoholic paralysis to be multiple neuritis; in these cases he had found the greatest variety of symptoms; in those cases of alcoholic neuritis we find neuritis alone, but cases have been reported where it has been combined with myelitis.

DR. MILLS said that he by no means denied the coexistence of the two diseases, but his desire was for the Association to discuss the different diagnostic points; he did not think electricity, as suggested by Dr. Lloyd, would be of great value; he felt convinced polio-myelitis began with sensory symptoms at times.

DR. FISHER read a paper on

A CASE OF BULBAR PARALYSIS.

The patient was a young married woman who had had several children; her family history was good. In the latter part of 1885, her speech became affected, the writer seeing her in February, 1886. The expression of the face then was characteristic of the disease, the lower lip hanging down and saliva flowing from the corners of the mouth, the tongue was small and atrophied and she could swallow with difficulty; examination of the larynx was almost an impossibility; reflexes were normal, the disease being confined to the hypoglossal and lower portion of the facial nerve; speech at length became utterly impossible, the mind was not affected, but the patent was very excitable and emotional. Emaciation then commenced, deglutition being extremely difficult, her food being confined to fluids. At night severe attacks of dyspnœa appeared, the patient being unable to cough.

At the autopsy the floor of the fourth ventricle, the region over the hypoglossal nerve was small and pale; the specimen after hardening showing an almost entire disappearance of the cells, the facial nerve was not involved in a marked degree.

Another case the writer quoted was that of a man who had syphilis, and who was thirty-five years of age. He had a sudden attack upon the left side of the face; the next month he had another attack upon the opposite side, also a cross paralysis; two months after, he could use the leg and arm again. One year later he had another attack but was not paralyzed, only remaining unconscious for four hours. Another case mentioned ended in recovery.

The writer presented microscopical specimens carefully prepared, showing the disappearance of the cells of the lower part of the facial nerve where the cells were found diminished in number; other sections were

made, but these were the only parts found to be affected in the first case mentioned.

DR. HAMILTON stated that he saw a remarkable case in 1881; it was well marked in the lips and tongue, but death did not occur until 1887; it was pronounced at the Neurological Society of New York where the patient was presented, as bulbar paralysis; at the end of three years it was pronounced hysteria; the patient had complained of symptoms a year before the speaker saw her; she finally died with all the symptoms of bulbar paralysis.

DR. THEO H. KELLY, New York, read a paper on

HYDROTHERAPY IN MENTAL DISEASES.

The object was to call a more general attention to the different forms of insanity and the methods of application of water in its many forms to these cases, as might be demanded. Reference was made to the past ages in which the use of water as a means of cure was much relied on; the Turkish bath in mental disease being often of great benefit. In mania, acute alcoholism baths are excellent, but in organic disease of the heart and lungs the Turkish bath is to be avoided or indulged but slightly. He considered that it diverted the blood from the central organs. The speaker mentioned the Russian vapor bath which averages from 105° to 110° as useful in some cases; the Roman bath in cases of melancholia; the bath, however, should not be indulged in when very tired or the stomach empty. In cases of nervous irritability the cold-water bath 40° to 60° is excellent, the patient being removed from the bed to the bath, remaining there for three minutes, and then again returned to bed. The tepid bath 80° to 95° and the warm bath 95° to 105° have also been of use in acute mania. The graduated bath should be reduced slowly from 98° to 60° or even 40°, this bath being the most acceptable and the most prompt means of reducing bodily temperature in alcoholic mania. The reader called attention to the wet pack, the shower bath, hot, warm, tepid and cold; also the douche bath, foot bath, sitz bath, the mustard bath, in the latter the genitals must be protected from the action of the mustard, three to six ounces of mustard being used to every thirty to sixty gallons of water. In some cases the use of hot or ice water bags is valuable applied to different parts of the body; in insomnia the hot spinal bag will often induce sleep. The ice cap or ice coil is almost universally used as a means of reducing temperature. The salt water bath, hot or cold, was referred to, those living from the sea-shore using the bag salt, five pounds of the salt to fifty gallons of water.

In conclusion, it might be said that the indications of hydrotherapy in mental diseases are to control bodily temperature, to stimulate local and general circulation, to produce diaphoresis and the elimination of certain substances through the skin, to hasten tissue changes and improve general nutrition, to allay irritability of the peripheral nerves, to procure sleep and relieve cerebral anæmic and hyperanæmia, and in a measure to take the place of drugs.

Balneotherapeutics in insanity are admittedly employed only experimentally as yet, but they are becoming a more exact science and indispensable in the treatment of mental diseases, they deserve a much more extended employment than has yet been accorded them in this country.

The meeting then adjourned until July of 1888.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, AUGUST 25, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

PHYSICAL TRAINING FOR THE POLICE.

THE problem of what sort of exercise is best adapted to a general, all-around physical perfection (as distinguished from mere brachial, crural, gastrocnemial or other local muscular hypertrophy) is one which deserves, as it is fortunately beginning to receive, the most careful study of medical men. That some systematic treatment is for most men, and we may add for most children, necessary to this end is coming to be generally admitted.

Dr. George Homan, Medical Examiner for the police department of the city of St. Louis, has recently published the results of his examinations of the existing police force of that city, as well as of the new recruits offering for such service. His pamphlet contains one or two conclusions interesting in this connection.

We may remark in passing that the figures recorded by him as the result of the examination of 482 men showed the average physical measurements and weight of all the men examined to be as follows: Height 5 ft. 8.22 in.; mean chest girth at level of one inch above the nipples, 38.13 in.; expansibility of chest, 2.75 in.; girth of waist, 34.13 in.; and weight, 167.13 pounds. The individual maximum and minimum of these dimensions were as follows: Height, 6 ft. 3.50 in., and 5 ft. 3.62 in.; mean chest girth, 48.25 in. and 31 in.; expansion of chest, 4.50 in. and 1.25 in.; girth of waist, 50 in. and 25 in.; weight 279.50 pounds and 110 pounds.

He places very properly more stress upon the play of the chest wall as an indication of vital capacity than upon the absolute circumference of the chest, which depends on adventitious circumstances, as the amount of fat on the ribs, the prominence of the scapulæ, etc. His chest measurements of such recruits as were added to the force during the last two years, show that the average mean chest girth of 122 such recruits exceeded the average of the regular patrolman about one-fourth of an inch, while the average chest expansibility of the former exceeded that of the latter about two-thirds of an inch.

Now comes the important fact that as a nearly constant result of police service it was found that this respiratory advantage was gradually *lost, or much impaired*, often within less than a year after appointment, and from facts collected and observations made the writer confidently ascribes a very considerable share of the pulmonary disabilities, which he finds to be very common in the force, to the neglect by the department of means to maintain and develop this normal degree of respiratory capacity.

Aside from one hour's drill per week in the manual of arms during the winter months, no bodily or athletic exercise is required of a policeman other than that involved in patroling the district assigned to him, with the incidental exertion needed on his part to maintain law and order therein, the result being that there is usually plentiful foot and leg exercise to the neglect of other highly important parts of the body.

In repeated instances applicants for appointment coming from occupations requiring all-around exercise, such as porters, mechanics, teamsters, and in whom the respiratory apparatus was found to be of superior excellence as regards both free expansibility and normal breathing sounds, after six months' police service the normal expansion had decreased from one-half to one inch, or even more, and the comparative rigidity of the chest walls was accompanied by impaired or roughened vesicular murmur, with symptoms of circumscribed congestions, incipient catarrhs, and other signs of sluggish pulmonic circulation, the girth of the chest being usually not sensibly changed.

Dr. Homan expresses it as his opinion "that the omission from the department equipment of means for regular systematic chest and arm exercise, and the enforcement of their use as a necessary part of routine duty in any police force on a service-basis similar to the one in St. Louis, indicates a point of vital weakness, and that such lack constitutes an unguarded avenue by which a host of physical evils assail the municipal defenders of life and property.

"A fair degree of speed, with good wind-endurance is recognized as being a necessary physical qualification of the perfect officer, and these requisites can only be secured by appropriate gymnastic drill designed to exercise and harmoniously develop and preserve the entire body."

The writer further says that he has found excellent results in improvement of the chest-play and with it of the tendency to respiratory disorders, to follow the use of hand-weights, sand bags, clubs and other devices for symmetrical physical exercise, to the limited extent to which he has been able to secure their systematic employment. His conclusion is that a certain percentage of the waste to the municipality from pulmonary diseases in the police force is avoidable, and that a system of systematic training which should increase the average breathing capacity, say one-half inch per man, would lessen the total time lost by illness from lung diseases one-third, while the general gain in moral and physical power would be 50 per cent.

DEATH AFTER INOCULATION BY THE METHOD OF PASTEUR.

Two new cases of death after Pasteurization are reported. One of these individuals, belonging to Charente, died sixty days after being bitten, and forty-five days after undergoing Pasteur's treatment.

The second case was that of a woman, aged fifty-seven, named Guele, who was bitten by a mad dog March 27, 1887. The bite, which was about the wrist, was immediately cauterized. The patient went to Paris March 29th, and was submitted to anti-rabic inoculations for thirteen days. She then returned to her home in Lalonbère, where she was a servant in a family. It was remarked that her temper had become very irritable. About July 16th, the patient was unable to swallow liquids; on the 20th, her limbs became weak, and she fell to the floor. At this period the hydrophobia was well developed, and the patient died on the 21st.

EXPERIMENTAL RESEARCHES ON THE PRODUCTION OF ALCOHOLIC CIRRHOSIS OF THE LIVER.

At the meeting of the Society of Biology, held in Paris, July 16th, Straus communicated the results of some experiments which he had made, with the assistance of his interne, Blocq, on the artificial production in animals of alcoholic cirrhosis of the liver. His experiments pertained to twenty-four hares, in the stomach of which he had directly injected a daily dose of half-an-ounce of a mixture of absolute alcohol, and methyl alcohol, diluted with three parts of water. Immediately upon receiving this injection, the greater part of these animals fell as if paralyzed, and for several hours they lay in deep coma. When, after the expiration of a certain time, these animals were killed, the experimenters invariably found the usual lesions of alcoholic gastritis; thickening of the mucous membrane, ecchymotic petechiæ of the surface, etc., but what especially attracted their attention was the pathological condition of the liver. This organ did not present to the naked eye any very marked alterations; it was smooth on surface as well as on section; the acinic, nevertheless, were surrounded by a reddish gray line, and in animals that had been kept most of the time intoxicated for three or four months, the ultimate perilobular portal spaces were found infiltrated with embryonic cells. In hares that had been kept constantly subjected to the action of the poison for seven or eight months, the hepatic lobules were completely surrounded by a crown of connective-tissue cells, and the experimenters had before them typical cases of annular perilobular and monolobular cirrhosis. "Nothing," says M. Straus, "is more natural than this localization; the alcohol, coming to the liver by the finer branches of the portal vein might be expected, first of all, to exert a baneful action on points where its contact is most intimate." As for the hepatic system of veins (intra-lobular, sub-lobular veins, and hepatic trunks), it never, according to Straus's

researches, participates in the processes of alcoholic cirrhosis.

In the discussion which followed the communication of M. Straus, M. Magnan related the results of some experiments of his own in the induction of chronic alcoholism in dogs. In dogs that are made to take daily a certain quantity of alcohol mixed with their food, one will note after such ingestion, instant staggering, followed by paralysis with coma. When they come to themselves, these animals present oscillations of the head first, then of the limbs, a veritable trembling, resembling in every respect that of the chronic human inebriate. Moreover, these dogs have terrifying hallucinations, for in the night-time they will all at once betake themselves to barking and howling, as if in the presence of a real danger. In a word, alcoholism in the dog is the exact counterpart of alcoholism in the man.

MEDICAL NOTES.

— The United States consul at Palermo, in his dispatch dated Palermo, August 1, 1887, states that "during the week just closed only twelve cases and six deaths from cholera have been reported in the journals. . . . No public official reports have been made thus far, . . . but it is known that many more cases and deaths have occurred than those reported in the journals, a larger number, indeed, having come under my own observation. In view of the temper and character of the people, the authorities naturally desire to keep the matter quiet as long as possible. A few 'demonstrations' have been held, and the municipality threatened because of its having temporarily discontinued the free distribution of rice. Upon the occasion of former threatened epidemics in Palermo, Sicily has been practically quarantined and shut out from all other ports of Italy, thus ruining trade for months. This year, however, she is fortunate in having a Palermitan in the cabinet at Rome . . . to whom she is indebted for perfect freedom to enter Italian ports thus far, after inspection, disinfection, etc."

The United States minister at Copenhagen, in his dispatch under date of July 29, 1887, states that a quarantine order has been issued by the Danish Government July 18, 1887. "According to this order, the provisions of the quarantine law of March 31, 1885, are to be enforced in regard to ships coming from Sicily or Italian continental ports between the Capes St. Maria and Spartivento, and the importation of rags, etc., from these ports is prohibited."

— The New York Board of Health being appealed to by the Park Commissioners for some deodorizer which should keep down the stench from the gas-saturated earth turned up in sub-way excavations in New York City, conducted various experiments, and finally reported success from the use of bromine water, made by dissolving a pound of bromine in a barrel of water. This quantity of solution, costing $1.00, is said to render two hundred feet of trench free of nuisance.

— The following ingenuous certificate was lately given by a hospital externe to a patient who requested a document to show his incapacity for work: "This is to certify that —— —— has been under treatment here for five weeks and therefore is unable to work."

— A Western contemporary says: "Country physicians save more money every year, on an average, than city doctors. Their minds are free, their consciences easy, and their pocket-books flush, even if they cannot 'put on style,' and hold prominent college and government positions."

—In the Pitti Palace, at Florence, is a table, says the *Medical Press*, which for originality in the matter of construction and ghastliness in conception, is probably without a rival. It was made by Giuseppe Sagatti, who passed several years of his life in its manufacture. To the casual observer it gives the impression of a curious mosaic of marbles of different shades and colors, for it looks like polished stone. In reality it is composed of human muscles and viscera. No less than a hundred bodies were made use of for the material. The table is round, and about a yard in diameter, with a pedestal and four claw feet, the whole being formed of petrified human remains. The ornaments of the pedestal are made from the intestines, the claws with hearts, livers, and lungs, the natural color of which is preserved. The table-top is constructed of muscles artistically arranged, and it is bordered with upwards of a hundred eyes, the effect of which is said to be highly artistic, since they retain all their lustre and seem to follow the observer. Sagatti died about fifty years ago. He obtained his bodies from the hospitals, and indurated them by impregnation with mineral salts. To add to the horror which such a piece of furniture is calculated to inspire in the minds of most people, the fate of Count Rittaboca, its last owner, may be related. One Christmas Eve he and his friends were playing cards on this table, when suddenly he jumped up, pale and agitated, overcome by the fixed gaze of these petrified eyes. Yielding to a sudden attack of violent mania, he stabbed himself and fell upon the table. His heirs, as may be imagined, were very pleased to sell this funereal object to the Government, who installed it in its present situation.

BOSTON.

— The death-rate last month in Boston is said to have been the highest on record. Eleven hundred and nineteen persons died in that month, whereas the number for July, 1886, was only 889. Figuring on a basis of 400,000 population, the rate per 1,000 inhabitants was 33.57 per cent. last month. The mean temperature during the month was 73°. It was 73° in July, 1873, and 73.8° in July, 1876; but in those years the death-rate was not excessive. The comparative humidity, however, was very striking, for whereas in 1873 it was 66.4°, and in 1876, 69.4°, this year it was 77°, showing the heat of last month to have been the most oppressive and fatal of any month for fifteen years, which is as far back as the table goes. The

mean barometer during the month was 29.98, the highest (July 5th) 30.20, and the lowest (July 10th) 29.54. The highest temperature was 95° (July 2d), the lowest 61° (July 10th). The greatest daily range was only 26°. Over half of the whole number of July's dead were children under five years of age, while almost half were very young infants. The number dying under one year old was 417; under two years old, 519; under five years old, 567. Diarrhœal diseases carried off 222 under one year old, 263 under two years, 268 under five years old, and 292 of all ages. Cholera morbus killed 8 persons last month, against 6 in July, 1886; and cholera infantum killed 233 last month, against 170 during the July before.

NEW YORK.

— Among the papers of interest read during the closing days of the meeting of the American Association for the Advancement of Science, was one read by Prof. Albert R. Leeds on "The Scientific Basis of the Feeding of Infants," in which he expressed the opinion that the mortality among bottle-fed infants was largely due to the kind of food ordinarily given them, which he believed to be physiologically as unsuited to the nutrition of a human infant as grass and hay were to the nutrition of a young calf deprived of its mother's milk. Prof. C. M. Woodward, Director of the Manual Training School of St. Louis, read a paper on "The Methods and Results of Manual Training," in which he considered the methods of the manual training schools, the economic results of manual training, the difference between manual training schools and European trade-schools, and the progress of manual training since the meeting of the Association at Philadelphia, three years ago, when the subject was discussed. Prof. J. W. Powell, of Washington, Director of the United States Geological Survey, was elected President of the Association for the ensuing year, and F. W. Putnam, of Cambridge, Mass., Permanent Secretary.

— The seventeenth annual convention of the New York County Superintendents of the Poor was held at Babylon, Long Island, August 15th and 16th, when the abuses of the county almshouses and the obligation of the public to the dependent and helpless classes were ably discussed by Dr. E. H. Howard, warden of the Monroe County Insane Asylum, and others. Among the other papers read was one by Dr. Stephen Smith, Commissioner of Lunacy, on "The Insane Asylums of New York State."

— Dr. Moreau Morris, Chief Inspector of the Summer Corps of the Board of Health, reports that, during the week ending August 13th, the physicians of the Corps visited 4,561 tenement-houses, containing 30,704 families, and prescribed for 1,089 cases of illness, of which more than 500 were diarrhœal in character. One hundred and fifty-three complaints of the unsanitary condition of premises were made, and 3,164 circulars and 1,512 tickets for St. John's Guild free excursions were distributed.

Miscellany.

ON THE COMMUNICABILITY OF TYPHOID FEVER THROUGH THE AIR.

At the Medical Society of the Hospitals, session July 22d, M. Devaiz communicated the fact of an epidemic of typhoid fever which he had recently witnessed, and which seemed to show that this disease may sometimes be propagated by the air, as well as by drinking-water. The water of the locality had, in fact, been examined very thoroughly, without any micro-organisms being discovered. On the other hand, the dejections of the first patient attacked had been thrown, without previous disinfection, into a privy, near which slept the three persons who next fell victims to the disease. It seemed, therefore, probable that the typhoid germs had been transported by the air, and that it was to this vitiation of the air that the communication of the disease in, at least, some of the instances was due.

MEMBRANOUS ENTERITIS FOLLOWED BY INTESTINAL PERFORATION FROM ULCUS ROTUNDUM.

Dr. Rothmann described at the session on June 20th of the society for internal medicine, Berlin, (as reported in *Deutsche Medizinal-Zeitung*, No. 53, 1887) a case of a patient who died with intestinal perforation, who during life had passed those fibrinous masses usually described as characterizing membranous enteritis. The patient, who had been under observation for several years, suffered from intestinal obstruction, and had for nine years had bleeding hæmorrhoids for which he had been successfully operated upon. Soon after this, he was attacked with colicky pains accompanied with vomiting. He complained of pain in the left hypochondrium. The heart showed nothing abnormal. The pain passed off with a sensation as if fluids and gases were passing through a constricted spot in the intestines. At the same time with such sensations fibrinous masses always appeared in the dejections. Two years before, for the first time, there appeared evacuations of dark blood, which ceased after the use of ice and acetate of lead. After a considerable time they ceased, and appeared for the last time in January of the present year. The patient then rallied and looked well. No tumor was to be felt in the abdomen. On the night of June 16th, he was suddenly seized with the severest pain, became very pale and had a small and quick pulse. For the first time vomiting of blood occurred. The abdomen was hard as a board. There was a smothering sensation referred to the sides and the lower abdomen. The symptoms were clearly those of intestinal perforation. Operation was out of the question on account of the marked collapse. Death occurred in twenty hours. Post-mortem section showed round ulcer of the duodenum, and rupture *in loco*, adhesion to the colon at the lower part of the ulcer, while the tear took place at the upper part of it. In the colon was a slight stenosis which evidently corresponded to the place the patient had described as feeling narrowed. There was no other lesion in the colon.

Correspondence.

EXCESSIVE HEAT THE EXCITING CAUSE OF TUBERCULOSIS.

BUFFALO LITHIA SPRINGS, August 11th, 1887.

MR. EDITOR, — In the *Boston Medical and Surgical Journal* of August 4th, appears a communication on "Excessive Heat the Exciting Cause of Tuberculosis," by Dr. Thomas H. Buckler.

This is a subject of great interest to the profession at large, especially to those who are accustomed to practice during the winter months in southern countries, such as Georgia, Florida, Bermuda, Riviera and Italy, where invalids suffering from pulmonary diseases most do congregate. My experience has been that the tuberculosis deposit which undoubtedly takes place during the heated term, may remain in the system much longer than the setting in of cold weather and not develop till the following spring. I refer only to cases of acute miliary tuberculosis. In one of those occurring in my own practice, the disease did not make its appearance until the latter part of March of the next year after an excessively hot summer.

If Dr. Buckler has not already done so, I think he will find by examining the reports of the Charité Hospital, at Berlin, that the mortality from acute miliary tuberculosis is much greater during those winters preceded by excessively hot summers. In many of these cases the anamnesis is unable to reveal the slightest hereditary taint, demonstrating conclusively that excessive heat was the direct exciting cause, as Dr. Buckler suggests. It is strange, however, that this, as it seems to have done, *should* have escaped the observation of German scientists, who although recording a higher rate of mortality from acute miliary tuberculosis after an exceeding hot summer, do not ascribe the cause of this mortality to excessive summer heat, nor indeed connect the two factors in any way, but seek an explanation of it in hereditary taint and the cold of the succeeding winter. Antithetical, however, is the query whether there are not more consumptives in England than in any other country in the world, in proportion to the number of inhabitants, and less sunshine? It is stated on the other hand, that the mortality from consumption in St. Augustine among those living there all the year round, is much greater than in towns of the same number of inhabitants farther North, — a fact easily accounted for by the excessive summer heat prevailing in Florida.

We are referring, as noted, mostly to acute miliary tuberculosis, excluding chronic phthisis. If now we regard the meteorological differences of climate in England, we find the summer heat relatively as excessive as elsewhere, and doubtless the exposure to it as great, proportionately, as in other countries, although the mean temperature throughout the year may be lower. The antithesis is therefore not real, but only apparent, and the case of excessive summer heat as the exciting cause of tuberculosis is a clear one. The proverbial antipathy of the Italians to going in the sun may account for the small number of cases of acute miliary tuberculosis occurring among them. Avoiding exposure to the sun's rays in hot weather seems almost too simple to be regarded as a prophylactic measure, yet in view of the above facts it is unquestionably a very valuable one. Yours very truly,

G. HALSTED BOYLAND, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 13, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Northampton	12,896	7	2	28.56	14.28	—	—	28.56

Deaths reported 2,639: under five years of age 1,432; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 909, consumption 282, lung diseases 116, diarrhœal diseases 673, diphtheria and croup 72, typhoid fever 60, malarial fever 36, whooping-cough 31, scarlet fever 16, cerebro-spinal meningitis 11, measles five, puerperal fever 3, erysipelas one, small-pox (New York) one. From malarial fever, New Orleans 11, District of Columbia eight, New York seven, Brooklyn four, Philadelphia, Baltimore and Charleston two each. From whooping-cough, Boston nine, New York six, Philadelphia, five, Baltimore four, Pittsburgh, and Milwaukee two each, Brooklyn, New Orleans, and Nashville one each. From scarlet fever, New York six, Philadelphia three, Brooklyn and Pittsburgh two each, Baltimore, Milwaukee, and Lynn one each. From cerebro-spinal meningitis, New York three, Portland, Milwaukee, Cambridge and Somerville one each. From puerperal fever, New York two, Nashville one. From erysipelas, Brooklyn one.

In the 23 cities and greater towns of Massachusetts, with a population of 1,083,730 (population of the State 1,941,465) the total death-rate for the week was 27.83 against 30.01 and 32.86 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,214,099, for the week ending July 30th, the death-rate was 23 2. Deaths reported 4,115: infants under one year of age 1,754; acute diseases of the respiratory organs (London) 160; diarrhœa 921, whooping-cough 165, measles 121, scarlet fever 46, diphtheria 25, fever 24.

The death-rates ranged from 13.9 in Derby to 30.1 in Preston; Birmingham 19.9; Bolton 17.6; Bradford 22.3; Hull 17.0; Leeds 27.7; Leicester 25.9; Liverpool 25.3; London 24.8; Manchester 26.7; Newcastle-on-Tyne 24.6; Nottingham 17.5; Sheffield 22.6; Sunderland 14.5.

In Edinburgh 20.0; Glasgow 18.3; Dublin 30.9.

The meteorological record for the week ending August 13, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Aug. 13, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 13, 1887, TO AUGUST 19, 1887.

BAXTER, J. H., colonel and chief medical purveyor. Ordered to proceed from Washington, D. C., to New York City, on public business, and on completion thereof, to return to this city. Par. 5, S. O., No. 187, A. G. O., August 13, 1887.

WOLVERTON, W. D., major and surgeon, Washington Barracks, D. C. Granted leave of absence for twenty days. Par. 3, S. O., No. 171, Division of the Atlantic, August 16, 1887.

BYRNE, CHARLES B., captain and assistant surgeon, Washington Barracks, D. C. Granted leave of absence for one month, with permission to apply for an extension of one month. Par. 4, S. O., No. 171, Division of the Atlantic, August 16, 1887.

WILSON, GEORGE F., captain and assistant surgeon. Granted leave of absence for fifteen days. S. O., No. 78, Department of Dakota, August 8, 1887.

DIETZ, WILLIAM D., first lieutenant and assistant surgeon. Granted leave of absence for two months, with permission to apply for an extension of one month. Par. 7, S. O., No. 189, Headquarters of the Army, A. G. O., August 16, 1887.

MCCAW, W. D., first lieutenant and assistant surgeon. Relieved from temporary duty at Fort Riley, Kansas, and ordered to his proper station, Fort Leavenworth, Kansas. Par. 3, S. O. 84, Department of Missouri, August 15, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING AUGUST 20, 1887.

ROBINSON, L., medical inspector. Placed on retired list.

GARDNER, J. E., passed assistant surgeon. Detached from Naval Hospital, Norfolk, Va., and ordered to the Fish Commission Steamer "Albatross."

MARTIN, WILLIAM, assistant surgeon. Ordered to Naval Hospital, Norfolk, Va.

REYPEN, VAN, W. K., surgeon. Appointed medical Inspector from August 16, 1887.

SIMONS, M. H., passed assistant surgeon. Appointed surgeon from August 16, 1887.

SOCIETY NOTICE.

The Annual Meeting of the AMERICAN ACADEMY OF MEDICINE will occur at Washington, D.C., beginning Wednesday, September 3d. The Third Annual Collation will be served at the Hotel Arlington, at nine o'clock on that evening.

RICHARD J. DUNGLISON, M.D., *Secretary*.

OBITUARY.

SUMNER PUTNAM, M.D.

Sumner Putnam, M D., a prominent physician, of Montpelier, Vermont, well known throughout the State, died August 20th, aged sixty-nine years and six months. He was a member of the State Legislature from Greensboro in 1857 and 1859; had been the medical examiner of the National Life Insurance Company since 1876; had been President of the Vermont State Medical Society, and was treasurer of that organization at the time of his death.

BOOKS AND PAMPHLETS RECEIVED.

THE TRAINING OF NURSES IN PRIVATE PRACTICE.[1]

BY ALFRED WORCESTER, M.D., OF WALTHAM.

THERE is a widespread belief that in sickness, as much depends upon the nurse as upon the physician. This belief is founded partly upon fact; for the nurse is the physician's lieutenant, and, of course, it is of as much importance that the medical orders shall be properly executed, as it is that they shall be properly given. But such comparisons evince entire ignorance of the physician's responsibilities. It is his duty not only to give proper directions for the management of every patient under his charge, but also to see that his orders are intelligently obeyed. There is no excuse for him in the fact that trusty agents are not at his hand; for it is his business to provide them, and until he can be sure of intelligent, faithful nursing service, he must not undertake the management of more cases of sickness than he can in person superintend.

Where the family or the friends of the patient undertake the nursing service, the physician is partially relieved of responsibility for any improper execution of his orders. It is his duty, however, in such cases to point out the disadvantages of such untrained nursing, if discovered, and to be then ready to supply suitable nurses, if wanted.

In times of war and in the hospitals, this need of trained nurses has been recognized and met. Thirty-three years ago the Crimean war gave to the world Florence Nightingale, and now, under the banner of the Red Cross, her followers stand ready in every civilized country of the world, to imitate her immortal example. Twenty-five years ago the New England Hospital for women and children began in this country the training of nurses; and now scarcely a single hospital can be found that is not reaping the advantages of trained nursing service. Nor are these advantages limited to the hospitals. Trained nurses find an increasing demand for their services in private practice. In no other department of labor is the standard of excellence so rapidly rising. Nursing is already a profession, and no longer a trade of last resort.

One result of this improved nursing service, and of the increasing demand for it, is the high rate of wages that the graduates of the training schools find no difficulty in obtaining at the very beginning of their private practice. Only the more wealthy families can as yet afford to employ them. The whole question of wages, however, depends upon the proportion of the supply to the demand. And families in moderate circumstances will not be able to have better nursing service until the supply of trained nurses exceeds the present demand for them. When that occurs, the present prices will fall, and nurses on graduation from the schools will have to be content, as have young members of every other profession, to begin at the bottom, and not, as at present they can do, at the middle of the ladder of earnings.

Inasmuch as by far the greater part of our practice is among that class now deprived of the improved nursing service, ought we not to take measures to supply the increasing demand for it, and to further the spread of its great advantages?

It must be confessed that hitherto the medical profession has not only not taken the initiative in this reform, but has even impeded its progress. Training schools for nurses have been generally at first opposed by the hospital staffs; and the graduates of the training schools have often failed to satisfy the unreasonable expectations of the physicians first employing them. Undoubtedly some of this trouble has been due to the fact that the physicians have been only indirectly concerned in the nurses' training and, accordingly, have not held themselves responsible for the nurses' advancement after graduation. Nor has it been thoroughly understood that the training the new order of nursing rests upon is designed simply to furnish intelligent lieutenants. Without explicit orders, correcting criticism, and the encouragement of confidence, very likely the old-time nurse will do as well as the best trained nurse.

On the other hand, it cannot be denied that the trained nurses on leaving the hospitals have shown an inability to adapt themselves to the varying service of different physicians, and to the circumstances of private practice. This fault is evidently due to the present methods of training, and can be remedied by sending the student nurses out into private practice, under physicians whose coöperation in their training can be secured.

But it is surely unnecessary at this day to dwell upon the slight disadvantages of the new order of nursing. And it is not so much the purpose of this paper to discuss the possible improvement in the present training schools as it is to demonstrate the way in which the supply of trained nurses can be so increased that their services may be had in every village of the land. At present, they can be had only in the larger cities, and even there only the rich can afford their services. Their number, it is true, slowly increases, but not nearly as many nurses as physicians are graduated each year; while, in order to supersede the untrained nurses, it would be necessary to provide probably three times as many trained nurses as there are physicians depending upon their services. It is evident that this large supply, which must be provided before their employment becomes general, cannot be furnished by the present methods of training. The schools connected with the hospitals can train each year only as many nurses as are needed for the work of the hospitals,— a number much less than that of the yearly graduates in medicine.

If, then, new methods of training must be adopted, in order that the growing demand may be met, and that even in the families where the income is small, the patient and the physician may have the great advantage of trained nursing service, it is surely incumbent upon the medical profession to devise and to inaugurate these new methods of training. This duty rests primarily upon the country doctors. In the larger cities the hospital training schools can furnish nurses for the wealthy, and physicians can send their poorer patients to the hospitals, or avail themselves of the excellent system of district nursing — the latest flower in this springtide of charities. But in the smaller cities, and in the towns and villages, the physicians, if they desire the great advantages of this new dispensation, must train their own nurse. It is one of the many new duties that have fallen upon the med-

[1] Read before the Massachusetts Medical Society, June 8, 1887, and recommended for publication by the Society.

ical profession; and it is therefore desirable to have some general plan for its performance.

Fortunately there is no trouble nowadays in finding young and strong women well fitted and eager for such training. The schools in operation have long lists of applicants who wait their chance to enter. Let it be known in any community that the physicians contemplate instituting a training school, and candidates in plenty will come forward. But they have read "Sister Dora," and perhaps Florence Nightingale's famous notes, and although they would prefer not to leave their native towns and their friends, they nevertheless desire thorough training. They stand precisely where the would-be doctors stood a hundred years ago, before medical schools were to be found: they want the physician to teach them. They will gladly work hard for wages that will barely support them, they will gratefully give to the physician most loyal, hearty service, if meanwhile they can be learning the art of nursing. Let us consider how this should be taught.

From the general similarity of the two professions of nursing and of medicine, it is evident that, for excellence in either, much the same kind of training is requisite. The difference between them, however, relieves the nurse of the responsibility of deciding what is the nature of the patient's trouble, and what should be done to relieve it: her only duty is to carry out the treatment ordered, and to note the different symptoms as they occur. The nurse, then, may well be ignorant of the theory, but she must be somewhat acquainted with the practice of medicine. She need not know in any given case why catharsis is advisable, but she must know what to expect when a cathartic is given.

The only exception to this general rule is in the matter of emergencies. In this department, it is necessary to drill the nurse so thoroughly that she will always have her wits in working order, whatever her patient's danger may be. There is no use in expecting her to remember blind rules. She must be taught the principles upon which the rules depend. Better far that the nurse shall remember the blood-starved condition of the brain in syncope, than that she should remember any rule for its relief. She must understand the underlying principle, if common-sense treatment is expected of her.

But training for emergencies, happily, demands only a small fraction of consideration. In order that the nurse in general practice may be able to carry out the medical orders intelligently, and report intelligibly the changes that take place during the physician's absence, she must have a working knowledge of elementary anatomy and physiology; of the general progress of the common diseases; and of the effects of the more powerful drugs.

Student nurses should, therefore, be taught enough anatomy, that they may understand the general workings of the body, and be able to use and to understand anatomical terms descriptive of the body's surface. Some knowledge of the structure and function of the lungs, for instance, is prerequisite to any satisfactory realization of the necessity of pure air. And it is a matter of more than mere convenience to all concerned that the nurse and physician shall be able to understand each other's use of the words stomach and abdomen.

In the hospital training schools, the student nurses may, perhaps, safely be left to learn what it is important for them to know about the different diseases, as these diseases are met in the wards; but in the country schools, where the nurses' experience is more slowly acquired, they must be taught, before the disease is met, its general characteristics. The special nursing required in typhoid fever, for example, must be taught beforehand, if the nurse is expected to take the best care of her first typhoid patient; and this can best be taught by describing the nature of the disease. The medical student is taught not only how to treat, but how to diagnosticate diseases that he has never seen; and there is no reason why nurses should not likewise be taught the special nursing needed in diseases they have not seen.

As regards materia medica, it is not so plain how much and how little nurses should be taught. The bugbear of the nurse's meddling in the physician's province must not prevent her being taught, at least, enough about drugs to prevent her from making grave mistakes in administering medicine. Not only is it convenient, but it is often necessary, to leave medicine, opium, for instance, in the nurse's hands, to be given *pro re nata* or *si opus sit*. In such cases, the nurse must be able to recognize the effects of the drug, and also the indications for its use. There is no danger of the trained nurse's knowing too much, and the more knowledge of medicines she obtains, the less likely will she be to attempt to prescribe them.

The instruction in these branches, if it is to be as systematic as it should be, must be given by the physicians in regular lesson hours. The student nurses can be assembled at their headquarters on certain afternoons or evenings. And, except when in charge of the very sick, it is a benefit to both nurse and patient for the nurse to go out for the freshening walk, and for the stimulus that the lesson gives; and again, these meetings of the student nurses with the physicians are beneficial to both. The nurse feels her instructor's interest in her advancement, and shares somewhat the enthusiasm of his high calling. The physician, on the other hand, finds it not in the least a disadvantage to be thus forced to review his foundation studies; he acquires a higher appreciation of the importance of the sister-art of nursing; he can realize and sweep away the obstacles to the nurse's success. A good working basis for both is thus established, which, in times of anxious watchings, brings forth the fruit of comfort a hundredfold.

Besides this groundwork that nurses should be taught by their medical instructors, the arts of cooking for the sick, and of keeping the patient and the sick chamber in exquisite order, must be taught them by women who are themselves proficient. The multitude of little ways of giving comfort to the sick, discoveries accumulating rapidly and being disseminated by books, and now also by the nurses' journal, *The Nightingale*, can, after all, be best taught by actual example. In these exceedingly important branches of the nurses' training, the students in the hospital training schools have the advantages of working with trained nurses, and also with nursing their patients in surroundings especially adapted for the purpose. The latter advantages can be had in the country training schools by making a miniature hospital out of some tenement, where a few patients may be collected, and it is absolutely essential in the country training schools to have, at least, the partial service of a trained nurse in teach-

ing others to be nurses. Such a teacher can be the queen of the miniature hospital, and at the same time, at the option of the physicians, can follow them on their rounds, visiting the bedsides where the student nurses are employed, to teach them there whatever, in her more experienced eyes, is needed.

In times of unusual healthfulness, the superintendent nurse can teach them how to write good clinical reports, how to take the temperature and pulse, and how to read aloud acceptably. The books upon nursing can then be studied. Upon an improvised manikin, bandaging, fomenting, poulticing, can be taught, and upon each other, the student nurses can practise massage.

This is a general outline of what every nurse should be taught. But the profession of nursing has already divided itself into specialties. That of nursing the insane can be taught only in the asylums, for physicians themselves have to look thither for the glimmering light of what little has been discovered about the comforting care of minds deranged. It is a matter for general rejoicing that the training school at the McLean Asylum, the pioneer school of its kind, is already furnishing trained nurses for these saddest cases.

Monthly nursing, however, will always be the chief specialty, and in no other department is trained service so fruitful of comfort and security. I need not set forth again in detail what monthly nurses should be taught, for I have done that in my manual upon the subject, but I want to call attention to the excellent opportunities physicians have in their private practice to train nurses in this branch. And, after once showing the student nurse how to prepare the bed and how to dress the patient, how, after delivery, to remove all traces of the labor, and how, during the confinement, to manage the little details of bathing, giving enemas, catheterizing, bandaging the breasts, etc., the physician's work becomes delightfully lightened; nor only this; his patients, also, are relieved in large part of the usual annoyances and ugly features of midwifery cases.

The general plan of a new kind of training school is no longer visionary. Such a school is already in most successful operation in Waltham, the youngest city of Massachusetts. Its first class has lately been graduated. It is not fitting for me to sound their praises; nor need I here, for they have already won honorable mention in the service of many members of this Society. But as an illustrative case, as a demonstration of the feasibility of the plan, I venture, in closing this paper, to report the history of the Waltham Training School.

The scheme originated in the local meeting of the Fellows of this Society. In the winter of 1885 a meeting was called of all interested in the project. Three lady managers were chosen, to whom all the details of management were entrusted, and to whose assistance the success of the school is greatly due. A class of seven student nurses was formed, three of whom have completed the two years' course of training. During their first year they served only under the physicians connected with the school, and they were obliged to assemble in the classroom on five afternoons of the week for lectures and lessons. During the second year they served also under other physicians and in neighboring towns, until the last month of their course when they were again assembled for reviews and examinations previous to their graduation.

A second class of eight is now in process of training, and soon a third class is to be formed, for which there are already many applicants. The student nurses are paid, beside their board, $9 per month the first year and $12 the second year. And the school charges respectively $7 and $10 per week for their services where the patients can pay; where they cannot, the nursing service like the medical attendance is gratuitous.

The total earnings the first year amounted to only 90 *per cent.* of the expenses, and the management had to draw upon a guaranty fund that had been established to meet any deficiency; but in the second year the earnings exceeded the expenses. Meanwhile the friends of the school have fitted up a dormitory for the student nurses in connection with the private hospital that has grown out of the original scheme.

It is not, however, because of its financial success that claim for attention is made; nor because of the deeply gratifying effect that such training has upon the student nurses in bringing out into perfect blossom that latent womanhood. For in both of these directions great success has been before recorded. Attention is called to the Waltham School because it is felt that a great and general want has been fully supplied. The physicians have only to call, and the nurses come, — to give their orders, and they are obeyed.

In destitute families where hitherto the hard alternatives have been for the physicians to do the nursing service themselves, or to let the cases go from bad to worse through default of proper care, the student nurses now go gladly for day or night service to carry into effect the physician's good intentions. It is in this kind of service that full warrant is found for appealing to the charitably inclined for the little money that is needed to establish such training schools.

THE IMPORTANCE OF EARLY RECOGNITION, DIAGNOSIS AND SURGICAL TREATMENT OF TUMORS OF THE BLADDER.[1]

BY GEORGE W. DAVIS, M.D., OF HOLYOKE.

As the methods of examination of the bladder and the means of investigating its diseases are becoming more numerous and exact, results are likewise becoming more positive and certain; diseased states and pathological conditions, formerly not known to exist, are now recognized and understood. With the present rapid development of surgical knowledge, let us hope that attainment to that degree of expertness which shall secure more satisfactory diagnoses and treatment of these obscure conditions (conditions most distressing and fatal), is near at hand.

It is quite possible that the bladder is more frequently the seat of tumor than is usually supposed.

Abnormal states of this organ are often surrounded with so much obscurity as to make diagnosis difficult or uncertain, and it is not improbable that tumor is sometimes overlooked.

At the present time the literature of tumors of the bladder seems very scant; but the reports of cases, and of the removal of such growths are becoming more frequent.

During the years 1882 and 1883 papers were pre-

[1] Read before the Massachusetts Medical Society, June 7, 1887, and recommended for publication by the Society.

sented to the Medico-Chirurgical Society, in London, by Sir Henry Thompson, calling attention to a new procedure for exploring the bladder, which he named digital exploration of the bladder, or external urethrotomy. This consisted of making a central perineal opening into the membranous portion of the urethra, just large enough to admit the index finger, which being introduced was able to explore the cavity of the bladder and its walls, in very much the same manner, and with nearly the same facility, as in customary examinations of the bladder of the female, through the dilated urethra.

Several cases were cited where the objects of the operation were fully realized, the entire mucous surface of the bladder coming within reach of the exploring finger, so that all the knowledge possible to be attained by the sense of touch was readily secured.

Tumors were in several instances discovered; their size, shape, consistency and location readily ascertained; their degree of hardness, manner of attachment, and much other useful information obtained, rendering the possibility of their removal a question for intelligent consideration.

Other cases were cited where only negative information was obtained, nothing important being found, yet the symptoms were either cured or much relieved.

He also pronounced the exploration almost without danger. The operation being quite simple and easily made, and being presented and advocated by a surgeon of such universal experience and unquestionable authority, appears to have at once taken a place among justifiable surgical procedures.

Opening the membranous urethra had long been done in stricture, retention, etc., but the idea of making such an operation merely to furnish a way into the bladder for diagnostic purposes was new — and excited much interest.

It seems that Professor Volkmann, of Halle, at nearly the same time and independently of Mr. Thompson, made the same exploration, and in Germany it is often designated as the Volkmann-Thompsonian operation.

With the description of his method there was given by Mr. Thompson a list of tumors found and removed, some through the wound of exploration.

The attention of the profession being thus forcibly called to the subject, tumors have come to occupy a more prominent place among the possible or even probable causes of intractable and obscure symptoms referable to the bladder, and so a new field for surgical culture has been opened and a new sphere presented for the relief of cases which have heretofore remained unrecognized and been given over as incurable.

It would seem, however, that Thompson's exploratory incision has not met with much favor in France or Germany, the supra-pubic or *sectio alta* being almost always preferred by Continental surgeons. Enlarged prostate and great obesity are conditions which interfere with its successful performance.

The bimanual examination of the bladder, sometimes mentioned in connection with the name of Volkmann, is much relied upon by all surgeons, and should never be neglected in any case of doubt. It is made with one or two fingers of one hand in the rectum, the other hand firmly pressing into the pelvis from above the pubes, the weight of an assistant often being necessary to aid in sufficiently forcing the pelvic contents down upon the examining fingers. An anæsthetic is indispensable in this manner of examination, as it is in examination *viâ* the median perineal incision of Thompson. The bladder must be quite empty, and unless there is much obesity a tumor of any considerable size and consistency can hardly escape discovery.

An encysted calculus which has escaped the sound may be thus discovered.

A paper was read by Dr. Max Nitze, of Berlin, at the Berlin Medical Society, Jan. 5, 1887 (reported in the *Berliner Klinische Wochenschrift* of this year, Nos. 8 and 9), in which he gives a careful resumé of the various methods of examination of the bladder, commenting upon the relative advantages of each, but more particularly describing his own method of exploring the cavity and inner surface of the bladder by the sense of sight.

This is made possible by an ingeniously arranged electric light, so introduced that it may be said to be combined with an endoscope, the inner surface being as distinctly seen as though it were examined piecemeal by the light of day after removal from the body. The bladder is made to contain a certain quantity of transparent fluid, thus opening the folds of the mucous membrane and presenting all portions of the mucous surface to view. The field at once visible is as large as a silver dollar, and is described as much resembling the image of the fundus of the eye when seen with the ophthalmoscope.

By changing the position of the mirror in this instrument or kystoscope, as named by Nitze, the entire surface is readily and quickly seen, and any abnormal condition easily recognized. By the use of cocoaine its use is rendered painless, and no other anæsthetic is necessary. The danger from heat resulting from the lamp in use is overcome by the circulation of a current of cold water.

Nitze cites cases where his method of examination has succeeded in discovering tumors which were removed, and he is confident its more general use would make earlier diagnosis possible, and so save valuable time.

At a meeting of the Medical Society of Berlin, Jan. 19, 1887, Professor Von Bergmann reported a case of tumor of the bladder, describing its symptoms, diagnosis and removal. In this case Nitze demonstrated to the satisfaction of Von Bergmann the practical working of his instrument, the latter speaking of it in terms of much praise, as being easily introduced and not distending the urethra or neck of the bladder more than a large-sized catheter, and in this case not occasioning any hemorrhage. (See *Berliner Klinische Wochenschrift*, No. 6, 1887.)

If we accept the statements of Nitze and Von Bergmann, we shall be forced to believe that most incisions and severe proceedings for purely diagnostic purposes are soon to be laid aside, and the kystoscope is to reveal to the eye of the diagnostician the actual state, the size and shape of stones or tumors being readily seen and appreciated.

The symptoms in tumor of the bladder are such as suggest the presence of stone, stricture, prostatic hypertrophy, or disease of the kidney.

Dysuria and strangury are present in the course of the development of tumor, and are often the occasion of great suffering and anxiety to the patient, their severity depending largely upon the variety and

location of the growth, its size, the length of time it has existed, the extent of the irritation and inflammation, the relative acidity of the urine, and many other obvious conditions. Cystitis is sometimes present in such intensity as to mask the symptoms more directly proceeding from tumor.

Hæmaturia is perhaps the most constant symptom in tumor of the bladder, but this may result from other causes which must be excluded. Hæmorrhage from the kidney is usually attended with attacks of renal colic and other evidences of renal diseases. Stone in the bladder must be excluded, and search with the catheter or sound for stone may discover the tumor, an indefinite something being felt which does not give the positive evidence of stone. The old, long-beaked sound formerly used for exploration of the bladder is now giving place to the short-beaked catheter furnished with stop-cock so that any degree of distention may be secured.

Soft instruments are much relied upon for exploration of the bladder by many surgeons of large experience.

Should clear water recently injected into the empty bladder return tinged with blood, we have evidence that the hemorrhage is vesical. Fresh blood passing at the end of, or immediately after micturition, must come from the bladder or urethra. The possibility of diseased prostate is suggested by this symptom. Much hemorrhage will suggest the presence of a vascular growth, and the bleeding may be out of all proportion to the size of the tumor, death having resulted from the loss of blood from a tumor of the villous variety, scarcely larger than a pea. (See Coulson, page 115.)

Cases may be attended with attacks of more or less profuse hemorrhage, separated by intervals during which the urine is nearly or quite clear of blood, but often the hemorrhage is continuous and never profuse, slowly exhausting the patient.

Shreds of tissue or tufts of the villous growth may be discharged with the urine or caught in the eye of the catheter, and if examined with the microscope may make the diagnosis certain as to the presence of tumor, and the question of its malignancy may be thus decided. Malignant growths are more rapid in their progress, and the urine may contain evidence of their presence in the form of débris.

Continuous hemorrhage not relieved by treatment or rest and the recumbent position, is strongly suggestive of the presence of a neoplasm, either in the bladder or kidney.

M. Guyon, of Paris, calls attention to the frequent presence of varicocele in tumor of the kidney, and also insists upon search for evidence of increased mobility of this organ, which he states is present to such an extent as to be readily recognized by bimanual examination or palpation, balottment being perceptible even in the early stages of such neoplastic formations.

This sign is produced by placing one hand in front of the hypochondrium and exerting with the other slight and quick movements or shocks in the lumber region, this manœuvre sufficing to recognize the mobility of the kidney.

Direct examination of the kidney, however, is acknowledged to be often very difficult, even by Guyon, who claims that in the great majority of cases the diagnosis of bladder tumors can be established without operation, and relies largely upon the presence of hæmaturia as a symptom. He also says that when a simple catheterization is followed by a continuous bleeding of long duration, a tumor may be almost positively diagnosed.

The importance of an early diagnosis should be emphasized, for if the growth be *non*-malignant, the probability of its successful removal is much greater if attempted early, before it has attained to large size or occasioned destructive changes and exhausted the strength of the patient by prolonged hæmorrhage and suffering. If the symptoms are not yet so distressing as to make removal advisable, only good can result from a knowledge of its presence. In malignant growths of the bladder sufficiently advanced to occasion marked symptoms and admit of diagnosis, there can be little hope of a radical cure by operation, and the question to be decided is, Can an operation alleviate the distressing symptoms, and so become valuable to the patient?

M. Guyon has operated upon thirteen cases of malignant growth of the bladder, and reports that the symptoms determining operations were relieved in all. He states that malignant tumors have scarcely attained to the size of a pea before there is infiltration, and it is already too late to hope for radical cure.

Admitting the truthfulness of M. Guyon's statement, it does not weigh against early operation, as the differentiation between malignant and non-malignant cannot be early determined before operation in most cases.

In the February number of the *Journal de Medecine et de Chirurgie* of Paris, of the present year, was reported a case of epitheliomatous growth removed by M. Guyon, the operation being described as radical. It had not returned after six months. In this case the growth was as large as the end of the thumb and situated in the anterior superior portion of the bladder, so being favorable for Guyon's operation, which is always supra-pubic.

The allotted length of this paper will not permit a careful discussion of the various questions involved in the treatment of these cases, but I will in a general way briefly refer to certain points.

No medication is likely to arrest the growth of neoplasms of the bladder, but if there is a possibility of syphilis in the case, the remedies known to act as its antidote should not be withheld. The general condition of the patient being cared for, the treatment must be of a local and surgical nature. Such symptoms as are particularly distressing must receive attention and be met by the usual remedies. An attempt must be made to control the hæmorrhage by rest and the horizontal position, and by astringent injections, of which, solutions of nitrate of silver and the prochloride of iron, varying in strength from one to three per cent., are most preferred. Antiseptic solutions for douching the bladder will be found indispensable.

The question of removal will be ever before the mind of the surgeon fully determined upon giving the patient every opportunity for relief. The cases of successful removal are now sufficiently numerous to make it no longer a question of doubt as to the duty of the surgeon in any urgent case presenting no marked contra-indications to operation. The usual tendency of this condition being to get worse, and after long months or years of increasing suffering to

finally terminate fatally, the surgeon is, in duty to the patient, bound to explore the bladder in such a manner as shall enable him to act intelligently.

If the sound or catheter, with bimanual examination or the kystoscope of Nitze, or such other methods as may be available, fail to make the condition plain, the bladder should be explored by the finger, and the question of choice between external urethrotomy and the supra-pubic operation must be decided upon.

If it is probable that much operative procedure will be required, as in the repeated passage of forceps for the removal of several growths, or a single large one, the higher operation should be at first selected, for its performance would be necessary, notwithstanding the urethra had been already opened, and we can hardly agree with Mr. Thompson in the opinion that the two operations do not add to the risks in the case. But if the urethra has been opened and a growth discovered, the thorough removal of which will necessitate too much manipulation to be safely done through the dilated neck of the bladder, the operator's duty will plainly be to make the high operation without delay.

There may be found in the July number of *Braithwaite*, 1886, a description of a sound invented by Mr. Thompson, which serves to support the bladder under these circumstances. The extremity of this sound is so notched that the surgeon can, while coming down upon it from above, recognize its exact position, and seizing with a hook the wall of the empty bladder can maintain its elevated position during the operations within its cavity.

The technique of cystotomy for the removal of tumor is mainly the same as in operation for stone.

Every case must present its own peculiar features. Several pairs of forceps with blades of varying width should be at hand. The margins of the blades should be slightly rounded to avoid the wall of the bladder.

The spoon of Volkmann is the proper instrument for scraping away such portions as cannot be completely removed with the forceps.

The removal of vascular growths is likely to be attended with much hæmorrhage, and the operator must be prepared for any emergency arising therefrom.

In the event of the tumor or tumors being very vascular in the female, it may be wise to operate through a vesicovaginal opening made for the purpose, but the surgeon should be very guarded in promising its speedy closure.

I have recently had the care of a woman who had tumors of the bladder of recurrent nature, which were several times removed by Dr. W. H. Baker, of Boston, through a vesicovaginal opening. Owing to a continuance of the symptoms and the recurrence of the growths, the fistula was not closed. At the time of my examination, what seemed to be several soft tumors of small size could be felt. At the post-mortem, six weeks later, there was found less of the gross appearances of tumor than I had expected. What had felt to the examining finger like soft tumors, was really a number of collections of villous tufts, very vascular and presenting to the eye, as well as to the finger, a velvety appearance. About one-fourth of the inner surface of the bladder was lined with this neoplastic formation.

Any one examining this specimen must be impressed with the difficulty necessarily attending the entire removal of the growth in a similar case.[2]

This very intelligent patient derived much relief from hot douches; but she learned by experience that they would, if too persistently used, aggravate the symptoms they were accustomed to relieve.

As will be remarked, no reference has been made to the pathology, and no attempts at a classification of tumors of the bladder — only certain points have been touched upon. Sufficient, however, may have been said to suggest the possibility of tumor to the mind of some one who may be searching for an explanation of certain obscure bladder symptoms.

GRINDER'S CONSUMPTION.[1]

BY FRANCIS J. CANEDY, M.D., SHELBURNE FALLS, MASS.

THERE have been employed in the grinding-room of the Lamson & Goodnow Cutlery Company, at Shelburne Falls, from thirty to fifty men and boys, for the past twenty-five years, giving an average of about forty.

During the past ten years there have died with chronic disease of the air passages twenty-three of these grinders. Seven Irish, seven English, six American, and three Germans, of which five were between sixty and seventy years of age, eight between fifty and sixty, three between forty and fifty, five between thirty and forty, and two between twenty and thirty, and there are now sick confined to the house, three, one English between sixty and seventy, and two Germans, one fifty-five years old, and another about thirty-five. There are still grinding five, in whom the disease is known to have made considerable progress.

This amount of fatal disease of respiratory organs in such a limited number of men, the majority of them considerably past the age at which consumption is most common, points positively to their occupation as a predisposing, if not an exciting cause, of no small importance, and my experience among these cases for the past ten or fifteen years, in the sick room and by the post-mortem table, has convinced me that the name of "grinder's consumption," given the disease by the laity, is a proper one.

That we all inhale no inconsiderable amount of dust in respiration is well known, and that certain occupations, as mining, wood and metal polishing, etc., cause the workers to inhale an atmosphere so loaded with dust of an irritating character as to produce specific lesions of the bronchial tubes and lungs, has become so well established that all the newer books upon diseases of the respiratory organs, treat of this condition under the somewhat hard name of *pneumonokoniosis*, a classification of which is based upon the nature of the dust inhaled, as *anthracosis* in coal miners, *siderosis* in iron and metal polishers, *tobacosis* from tobacco dust, or from the avocation of the sufferers as grinder's consumption, Potter's consumption, mason's and millers' lung. Of all these forms, none seem more certain or fatal in its effects, than the grinder's. Peabody, in some investigations made at Sheffield, England, making the average period they are able to continue their work thirteen years.

[1] Read at the May Meeting of the Franklin District Medical Society.

[2] The specimen was exhibited to the Society.

The morbid anatomy of grinder's consumption, as I have studied it in three post-mortem examinations, I have found as follows: The bronchial lesions are those of chronic bronchitis, with thickening of the bronchial mucous membrane, associated with ulceration and bronchial dilation, forming bronchiectatic cavities. These cavities, which are a marked feature in some cases, are said to be caused by a combined softening of the bronchial tissues, with traction from without by the newly-formed fibrous tissue.

Fibroid Phthisis. — The bronchial glands are enlarged, some of them to size of small walnuts, gray and gritty on section. Gray nodules of cretaceous matter, from the size of a pin's head to that of a pea, are found disseminated throughout the lungs. But the most distinctive lesions are patches of indurated lung tissue, the predominant form of pulmonary change being of the fibroid type: hardened districts of advanced cirrhosis occur, measuring two inches and upwards in length, breadth and thickness. On section they are gray, tough, and leathery, and covered in by a thickened and adherent pleura. In all of my cases I found quite large and irregular-shaped cavities in the base and posterior portions of one or both lungs, into which, and in some quite through the diameter of which passed bands of this same fibrous tissue.

In one case this process of cirrhosis and breaking-down of lung tissue, had so interfered with the circulation as to produce gangrene, and in several cases in which no post-mortem was made the atmosphere of the sick room has been intolerable for days from this same gangrene of lung. This fibroid induration of lung tissue is quite extensive, is found in both lungs, involving one-half or more of their entire substance, in some cases, and shades gradually into the healthy tissue.

The contraction of this new growth not only destroys the elasticity of the lungs, but actually constricts the areas of intervening healthy lung. The normal capillary circulation is, of course, seriously interfered with, or destroyed in those cirrhotic patches, and in proportion to their extent the entire pulmonary circulation becomes obstructed, and the right ventricle and the venous system distended, this condition of course, being greatly aggravated by exertion, thus accounting for the intermittent pulse, dyspnœa, dilated veins, and cold extremities which are so prominent in some very chronic cases. The course of these morbid processes is insidious and slowly progressive, and as in other forms of lung disease, is more or less modified by inherited tendencies, and such influences and habits as diminish vitality, or affect personal hygiene, especially the use or abuse of alcohol, three-fourths of my cases having been hard drinkers.

The earliest objective symptoms is cough, especially recurrent in winter, accompanied by a somewhat frothy and stringy expectoration, chiefly dependent upon the bronchitis, which is undoubtedly the first morbid process in grinder's consumption. Soon shortness of breath upon exertion, as walking up hill, is complained of, but an examination of the patient shows him to be without fever, and when quiet with no increased frequency of the pulse; this lack of all fever, even when pulmonary lesions are quite advanced being one of the strong points in the differential diagnosis between grinder's and tubercular consumption.

Cases frequently go on for years with no especial disturbance of health or evidence of the lesions taking place, excepting the cough and the inability to fully inflate the lungs, owing to the chronic interstitial inflammation going on in them. Sooner or later, however, this interstitial inflammation reaches a point in some portion or portions of the lungs, which not only destroys its ærating function, but so interferes with its nutrition, that the tissue begins to break down in a gangrenous or purulent process, and it is frequently not until this stage has been reached, that the case comes into the hands of the physician. We now find the man decidedly ill, with fever, coated tongue, entire loss of appetite, often a terrible cough, which produces great suffering from a circumscribed pleurisy, and if we have not been acquainted with cases of the kind in the past, we will probably make the mistake of thinking the trouble more acute than it will prove to be.

In several of my cases, exposure to cold and wet, especially while under the influence of drink, has served to result in a broncho-pneumonia, the starting point of the breaking up of the lung tissue, from which the man succumbed in from six months to two years. That this is liable to occur in lungs previously healthy we well know, but that it is much more likely to occur in grinder's is beyond question.

The patient is usually confined to his bed from ten to twenty weeks in this first attack, with quite constant fever, though with a temperature rarely above 102° and pulse from 80 to 90, entire loss of appetite, and progressive emaciation. After a month or six weeks an abscess will be sufficiently matured in the portion of lung producing the immediate mischief to find its way into a dilated bronchus, when the patient begins to expectorate large quantities of purulent matter, the fever begins to subside, the tongue cleans, an excellent appetite often follows, under the influence of which some flesh and considerable strength may be regained. The patient begins to sit up, and if it be warm weather, perhaps goes out of doors somewhat, though considerable cough and a profuse purulent expectoration usually remain; the matter probably coming partly from the breaking down of tissue from the walls of the abscess cavity, and partly from the bronchitis and bronchiectatic cavities before mentioned. But, as one might suppose from the pathology of the disease, this period of improvement never advances very far, though two or three of my patients have lived nearly two years after first coming into the bed, in pleasant weather dragging their emaciated forms about the streets, by the aid of a cane, and one patient doing considerable light gardening for one summer. Those who have the most courage to go out of doors live longest, but the most sanguine and determined succumb in the end to the inevitable exhaustion.

Two cases in the convalescent stage of one of these pulmonary abscesses died from hæmorrhage, blood bursting in a large stream from mouth and nose, destroying life almost instantly, from erosion of some large vessels. Aside from these cases I have never seen hæmorrhages.

All cases do not run this course characteristic of the formation of pulmonary abscess, though I think the greater number do. The progress of some cases is exceedingly slow, and covers a period of many years, some under my observation living ten years or more, after being compelled to leave the shop by their cough, most of the time in chronic invalidism, and dying at

last from the exhaustion dependent upon pulmonary disease. As to the treatment of grinder's consumption, little can be said that does not apply in the management of other chronic diseases of the air passages. Of course the first and most important step is to remove the patient from the influence of the exciting cause, namely, the atmosphere of the grinding room, but this, even when done early in the disease, though undoubtedly greatly prolonging life, often fails to save the patient, so persistent are these fibroid changes in the connective tissue of the lungs when once commenced. I have known three deaths from this disease to occur in men who had not worked at grinding or in a shop at all for ten years or more, and for the greater part of the time being considered able-bodied.

In a disease in which induration of tissue and new growth play such an important part as in this, the iodides, owing to their capacity for promoting absorption, naturally suggest themselves to us, but I have never observed any positive benefit from those that I have employed, the potassium and ammonium salts, though I admit, that owing to disturbance of the stomach I have never pushed them very far. For the cough and to promote expectoration of morbid matter, I think much of muriate of ammonia in a mixture combined with the carbonate, spirit of chloroform and licorice to cover the disagreeable taste of the ammonia. In many cases, owing to dilations and contractions of the bronchial tubes, it is very difficult for the patient to clear his lungs of the accumulations of muco-pus, which becomes thickened and blocked up in some of the sacculated bronchial cavities, giving rise to prolonged and exhausting paroxysms of very severe cough. In this condition, this combination of ammonia with a little spirit of chloroform, is more effective than anything else that I have ever tried.

Aside from the usual hygienic management of wasting diseases, as an abundance of nutritious food, large and sunny rooms, particularly sleeping rooms, all the exercise possible in the open air, bathing, cold sponging, etc., nothing is of so much value as the systematic and prolonged use of the pure cod-liver oil. If the prejudice that patients have against it, owing to the fact that most people who take it do not get well, can be overcome, and they coöperate intelligently and earnestly with their physician, their lives may be prolonged from one to three years by its use.

Cod liver oil being valuable as a nutrient, rather than as a medicine it is often given in doses too small to amount to much. Commencing with a teaspoonful, if no more can be digested at first, the patient should get up to from two to three ounces a day in six or eight weeks, this quantity to be continued for months. To quicken the weak and failing appetite, I have found nothing better than a combination of syrup of hypophosphites with dilute phosphoric acid and strychnia, taken before meals. But in spite of all treatment the inevitable tendency of the disease seems to be toward a fatal termination, and I have never seen any recoveries.

— Dr. Louis Heitzman, of New York, has had good success in aborting furuncles by the local use of an eight per cent. salicylic acid plaster, or salve. For the former, he uses empl. saponat. ℥ii, empl. diachyli. ℥i, and acid salicyl. ℥ii. For the basis of the salve, he prefers unguentum aquæ rosæ.

REPORT OF PROGRESS IN GYNÆCOLOGY.

BY F. H. DAVENPORT, M.D.,
Assistant in Gynæcology, Harvard University.

USES OF IODOFORM GAUZE IN GYNÆCOLOGY.

FRITSCH[1] uses nothing but iodoform gauze for tampons. For this purpose, he employs it of the strength of ten per cent., and this can be made stronger by the addition of iodoform powder or iodoform glycerine. The gauze is prepared in long strips, plaited like a fan, which are introduced into the vagina, and can easily be removed by the patient. It remains antiseptic from four to six days, longer than tampons soaked in five per cent. carbolic acid.

Fritsch finds this gauze of especial value in the palliative treatment of carcinoma, and, in contra-distinction to the method by irrigation, calls it the dry method. It more surely relieves the foul discharge, hæmorrhage, and pain, so that patients believe they are entirely well. Cases of cancer which had been sloughing for months were kept odorless until death occurred. In several cases, the uterus had been reduced to a mere shell, the inner surface of which was covered with abundant, somewhat anæmic-looking granulations.

Fritsch first curettes the diseased portion, then applies the Pacquelin cautery, and then, to control hæmorrhages and diminish the secretions, fills the cavity with iodoform tannin powder. A tampon is then placed in the vagina, which remains five or six days. Subsequent treatment consists in applying, twice a week, iodoform tannin tampons, or when a tendency to hæmorrhage continues, iodoform glycerine tampons, filling the cavity completely.

The author has also had good results with tamponing the uterus with iodoform gauze after the removal of sloughing portions of the placenta, or intra-uterine polypi. He has further used it in the treatment of endometritis of body and neck, and for the introduction of medicaments into the uterus; also to keep the edges of the wound apart in the operation of discission.

In cases of opening the peritoneal cavity, Fritsch has, for three years, used the gauze, instead of the drainage-tube. He has introduced a specially ingenious use of the gauze in the after-treatment of severe laparotomies, where there were inflamed or suppurating surfaces to be rendered aseptic, or in cases of extensive adhesions to control hæmorrhage. Such surfaces he first sprinkles with iodoform, and then places several layers of folded gauze tightly over them, bringing one end out of the abdominal wound. The capillary drainage is complete, and the disinfection within the abdominal cavity is secured as well by shutting the wounded surfaces off from the rest of the peritoneal cavity, by the rapid glueing together of the intestines.

In spite of his free use of iodoform, Fritsch has never seen a case of iodoform-poisoning.

TRACHOMA PUDENDORUM.

Prof. I. M. Tarnovsky[2] made an interesting communication on this subject before the Obstetrical and Gynæcological Society of St. Petersburg. As is well known, Professor Sattler has shown that the secretion from a trachomatous conjunctiva invariably contains micrococci, which differ from ordinary gonococci only

[1] Sammlung Klin. Vorträge, No. 288. Reported in Cent. für Gyn., No. 11, 1887.
[2] London Medical Record, April 15, 1887, from Russian Journal.

in size. Their cultivation and inoculation always produce true trachoma. He also found that when the gonorrhœal pus from the mother's genitals is introduced into the child's eyes, it gives rise either to purulent conjunctivitis or to trachoma. In view of these facts, Sattler came to the conclusion that trachoma had a gonorrhœal origin. Tarnovsky says that his extensive observations have shown that there undoubtedly exists a true "trachoma pudendorum."

The appearances found are on the mucous surface of the labia majora, and especially of the upper commissure of the labia nimora, and consist of small grayish or yellowish nodules, surrounded by a slightly hyperæmic halo. These, in time, grow paler, though they remain raised, and later, form groups, measuring three to four by one-and-one-half to two centimeters. When examined by the finger, they feel somewhat harder than the surrounding tissues, and as though there were sand under the mucous membrane. There is crepitation on scratching with an instrument, and the spots do not bleed easily. Without treatment, they may exist for years, disappearing from one spot to appear at another, and in old cases, the patch may become almost cicatricial.

The microscopical examination shows an "epitheliomatous papilloma," in the cells of which are enormous numbers of micrococci.

As regards the differential diagnosis, Professor Tarnovsky thinks the trachoma might be mistaken chiefly for milium, erosion of the papillæ, or granulating ulcer. The essential symptom is itching, "felt deeply within the vaginal entrance." It decreases from pressure on the genitals, application of cold and smooth bodies, increases at night in a warm bed, and, especially when situated near the clitoris, causes sexual desire, with tendency to masturbation. Sometimes there is no pruritus, but only an increase of feeling and excitement during coition. They sleep always on one side, with their thighs firmly pressed together, and drawn up to the abdomen. They like to sit or ride astride, or to drive in a shaky vehicle, with soft, elastic, springy cushions. Nothing of the kind is observed in cases of pruritus from other causes. It is most frequent in prostitutes, then in married women who have at some time had blenorrhœa, or whose husbands have had gonorrhœa, rarely in young girls or old women.

The best treatment is a net-like, superficial scarification, and subsequent painting with a solution of nitrate of silver, or sulphate of copper or zinc, or with a five per cent. solution of carbolic acid, or a solution of corrosive sublimate. Professor Tarnovsky considers trachoma pupendorum infectious, and thinks it alone may produce gonorrhœal urethritis in men.

STATISTICS OF TOTAL EXTIRPATION OF THE UTERUS FOR CANCER.

Dr. A. Martin [3] has collected statistics of the cases of total extirpation of the uterus operated on in his clinic, with reference to the radical cure. Of sixty-six cases operated on from 1880 to 1886, eleven, or eighteen per cent., died as a result of the operation. These cases are, of course, of no value as regards the question of a return of the disease, nor should the cases operated on in 1886 be considered. That leaves forty-four cases operated on before the end of 1885, where, microscopically, the whole of the disease seemed to be removed. Of these, twenty-nine per cent. had showed a return, and seventy-one per cent. were, at the time of writing, free from disease.

Separating these cases according to the three most common localities, we find that there were three cases of cancroid of the portio vaginalis, of which one showed a return, twenty-eight of carcinoma of the neck, with eleven cases of return, and thirteen of carcinoma of the body, with only one return.

A table is also given of twenty-eight cases of total extirpation, where from the first a radical cure was not to be expected. All had either died or shown a return of the disease, except one operated on in September, 1886, and the fate of one other could not be ascertained.

[3] Berl. Klin. Woch., No. 5, 1887.

ON CASTRATION FOR EPILEPSY.

Dr. J. Schramm,[4] after referring to all the cases of epilepsy treated by castration to be found in the literature, asks whether there are cases of epilepsy without pathological changes in the genital organs, in which the bringing about the menopause, has alone been able to effect a cure.

He recognizes the gravity of removing sound ovaries, and says that only the clearest causal connection between the menstrual process, and the epileptic attacks would justify the operation. He then gives the histories of two cases of a severe form of epilepsy intimately associated with menstruation as regards time of occurrence and intensity. Where other means tried through years had failed, and where the removal of, in the one case perfectly sound ovaries, and in the other, ovaries normal except for a cyst the size of a cherry in the right, was followed after a short interval by complete cessation of the epileptiform attacks. For the interesting details of these cases, the reader is referred to the original.

SIXTY TOTAL EXTIRPATIONS OF THE CANCEROUS UTERUS.

Fritsch [5] begins this interesting article with a reference to the rapidity with which the operation for the total extirpation of the uterus has gained a footing in Germany, and says that the time is passed when one need be proud of a series of good results as regards the immediate operation, and that the question now should be, "What is definitely gained by the operation?"

Fritsch found in Breslau a large per cent. of cases of cancer in young persons, six per cent. between twenty and twenty-five, nine per cent. between twenty-five and thirty, and the same between thirty and thirty-five. He cannot subscribe to Ruge's division of cancer of the uterus into three forms; at least he doubts that the several varieties can be always strictly differentiated.

As between the high amputation and total extirpation, Fritsch performs the latter almost exclusively. His objections to the former are the greater difficulty in removing the uterus from which the cervix is gone, and the frequent narrowing of the cervical canal and os after high amputation. He considers, on the other hand, total extirpation an easier and less bloody operation. Only when there is a very small nodule of disease which has been early detected, does he perform the high amputation.

The conditions under which he would perform total

[5] Berl. Klin. Woch., No. 3, 1887.

extirpation, are, first, mobility of the uterus. The presence of thickenings at the side he considers no contraindication, provided they do not fix the uterus, as they are not necessarily due to an extension of the disease. The apparent size of the cancerous growth is of minor importance, for often a large tumor, filling the vagina, is really confined to the lowest part of the vaginal portion.

He opposes preparatory operations such as removal of portions of the tumor by the knife or curette, and considers it theoretically at least probable that such procedures would favor the passage of cancer-cells along the lymph vessels, and thus render a return of the disease more probable.

The article then explains, in quite minute detail, the advantages of his method of operating, which has been described by Bokelman in a former number of the *Archiv für Gynakologie*. Its peculiarity consists in his first dividing the attachments of the broad ligaments to the uterus, then the anterior cul-de-sac, and lastly posteriorly. If the ovaries and tubes are easily reached he removes them, especially in young women. If the uterus is found to be so enlarged by the presence of fibroids as to render its removal per vaginam impossible, he does not hesitate to perform laparotomy. The bladder and uterus are very seldom wounded.

The results of his sixty cases are as follows: ten per cent. died in the clinic from the immediate effects of the operation, fifty per cent. were either suffering from a return of the disease at the time the article was written, or had already died, and forty per cent. showed no signs of return after an interval of from ten months to three years and two months.

The author does not consider the percentage of recoveries as a definite result, as the time since operation is too short, still as relapses are by far most common during the first year a fair proportion may be considered definitely cured. In conclusion, he says, that if we ask what is of the greatest importance in improving the prognosis, the answer is, "The assistance of the general practitioner. The earlier the disease is discovered the surer can it be cured."

DIAGNOSIS OF BEGINNING CARCINOMA OF THE CERVIX UTERI.

Dr. Stratz [6] in an article on this subject says that the perfected technique of the operative treatment of cancer of the uterus has rendered its cure possible, provided it is seen at a sufficiently early stage. It is, therefore, important to be able to make a diagnosis early. Even if certain symptoms, as profuse menstruation, leucorrhœa, pain, hæmorrhage following coition, with the exclusion of other causes point to carcinoma, still the difficulty of distinguishing beginning cancer from erosions will always exist. Ruge and Veit recommend the excision of a piece of the erosion for microscopical examination, and by this means making a diagnosis. But even microscopically, it is possible to recognize certain characteristic appearances which are peculiar to carcinomatous erosions. He gives four particular important signs:

(1) The diseased surface is everywhere sharply separated from the sound tissues; it nowhere gradually changes from one to the other.

(2) A difference in level between the diseased part, and the healthy can always be recognized.

[6] Zeit. für Geb. Med. Gyn., xiii, 1, 1886.

(3) The cancerous portions have always a yellowish tint.

(4) The malignant spots show small, yellowish-white, glistening raised points, at least in certain places.

THE INTRA-UTERINE GALVANO-CAUTERY.

Dr. Landowski [7] recommends the use of the electro-cautery in membranous dysmenorrhœa. He thinks the uterine disorder is frequently a cause of the general cachexia and debility which we usually find in women suffering from this disease. He has applied the galvano-cautery in two cases, after thorough dilatation of the os, the time chosen being five or six days after the cessation of menstruation. In one of the two cases the result was a complete cure; in the other the pain was relieved, but a small piece of membrane the size of a penny continued to be expelled at each menstrual period. This was, in his opinion, due to a small portion of the uterine wall, having escaped the action of the cautery.

M. Apostoli has also employed the intra-uterine cautery in a large number of cases of chronic neuritis and endometritis, with great success. It is not necessary to confine the patient to bed during the intervals between the applications, and improvement, as a rule, follows after a few sittings. He prefers this method over that of scraping with a sharp curette, as being capable of exact graduation, of being more easily localized, and of not being so instantaneous. The result of the cauterization is to cause the formation of a new and healthy mucous membrane.

Clinical Memorandum.

A COMPARISON OF SOME CASES OF CATARACT EXTRACTION, WITH AND WITHOUT IRIDECTOMY.[1]

BY CHARLES H. WILLIAMS, M.D.

At the present time, there is a tendency among operators to return to an older form of cataract extraction, in which the lens is removed without making an iridectomy, and these cases are reported in order to compare the results of a few operations with and without the removal of a piece of the iris, done as nearly as possible under the same conditions, and by the same operator. In the operation, as proposed by Daviel, the corneal wound was made downward, and the flap included more than one-half of the corneal circumference. Later, the size of the flap was reduced, and it was made upward, so as to be more protected, and kept in position by the upper eyelid. There was no iridectomy, and, after incising its capsule, the lens was made to find its way through the pupil by using gentle pressure over the lower part of the eye. The principal danger in this operation was the tendency for the edges of the flap to suppurate, and this process often extended to the rest of the cornea, so that some ten per cent. of the cases were lost from this cause, for the wound was so large that the nutrition of the cornea was interfered with. It was difficult to keep the flap

[1] Read before the Boston Society for Medical Improvement, May, 1887.

well in place during the healing process, and pathogenic bacteria found here a good soil for development. In order to avoid the suppurative danger, and to give an easier exit to the lens and its cortical fragments, Von Graefe proposed his operation, in which the cut was placed in the sclera, just above the cornea, and the upper part of the iris was excised before removing the lens.

This procedure reduced the cases of corneal suppuration to about two per cent., but the after-effects were not always satisfactory, for, apart from the optical defect caused by a large iridectomy, there was often irritation, or even sympathetic inflammation, caused by the proximity of the wound to the ciliary region, or to the incarceration of portions of the iris in the cicatrix. This led to a diminution in the size of the iridectomy, and to placing the wound more nearly in the sclero-corneal junction. In the operations now proposed, of which that of De Wecker may be taken as a type, the iridectomy is omitted, the wound is made to include the upper third of the corneal margin, and some form of antisepsis is used. He generally employs a solution of cocaine, with a small amount of corrosive sublimate, for an anæsthetic, washes the eyelids carefully with a solution of boric or salicylic acid, or the sublimate, carefully disinfects the instruments, and, after the operation is completed, covers the wound with a narrow layer of fine iodoform powder, drops a little eserine solution on the conjunctiva, to contract the pupil and diminish the danger of hernia of the iris into the wound, and closes the eye with a salicylated dressing.

In my cases, the corneal wound included a little more than one-third of the corneal circumference, the capsule was freely incised with a T-shaped opening, and no iridectomy was done. The anæsthetic was cocaine, two per cent., made up in a five per cent. solution of boric acid; and before operating, the conjunctiva and lids were thoroughly washed with a solution of iod-hydrargyrate of potassium, 1 to 10,000, and in my later cases, 1 to 5,000 has been used without irritation. This salt was chosen as a result of some experiments made by Dr. Miguel, who showed that the minimum amount of disinfectant required to prevent fermentation in a litre of sterilized beef-broth was: biniodide of mercury, 0.025; carbolic acid, 3.; bichloride of mercury, 0.070; boric acid, 7.5.

The biniodide (red iodide) of mercury is, however, very insoluble in water, and in order to use it, Panas has prepared a solution of biniodide of mercury 0.05, alcohol 20.00, water 1,000.00, which gives a strength of the salt of only 1 to 20,000, and, on account of the alcohol, seems to me a little more irritating than the solution used in these cases. The biniodide of mercury is quite soluble in solutions of the iodides, and, by mixing a given amount of this salt with a slightly greater amount of iodide of potassium, a solution can be readily made in water, which, when evaporated, gives the yellow iod-hydrargyrate of potassium.

When this salt is dissolved in water, a decomposition takes place, and we then get again merely a solution of the red iodide of mercury in the iodide of potash, so that, for practical purposes, instead of using the compound salt, which is not often kept by the apothecaries, it answers just as well to order:

Hydrarg. iod. rub.		02
Potass. iod.		05
Aquæ	200	00

which gives about a six-ounce mixture, of 1 to 10,000 of the mercurial salt.

To return to the operations: after the lens has been extracted, eserine was used in two cases, where there was a decided tendency for the iris to prolapse into the wound. In one case it retracted well, but in the other, No. 2, it was necessary to excise a small portion of the iris before bandaging the eye, and here it was found that the semi-fluid vitreous pressing behind the iris had kept it forced into the wound. In the other cases, the iris retracted well without eserine after the extraction of the lens, and no hernia formed in the course of the healing.

It has been stated by De Wecker that extreme care is needed after the operation to keep the patient perfectly quiet, and for this reason, he is said to decline to do this form of operation during the summer months; but as all the cases reported were done during June, July, and August, and the details of No. 8 show a most unusual amount of restlessness on the part of the patient, it would seem that this form of operation need not be declined for this reason, especially as, under the same conditions, it has given me better results than the modified Graefe.

In order to compare the results obtained by the two forms of operation, with and without an iridectomy, the average length of treatment and result of my Graefe operations done during the summer months for the previous five years is compared with the results from the modified-flap operations done last summer, much to the advantage of the latter. The hot, and presumably the least favorable, months of the year have been taken for comparison, since the conditions were there equal, and because, on account of my service at the Eye and Ear Infirmary during the summer, a number of cases could be collected.

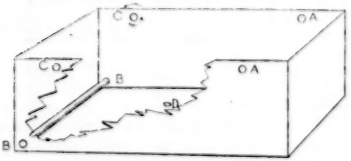
Modified Graefe Operations (with iridectomy).

Time of Operation.	Average Length of Treatment. Days.	Average Resulting Vision.
June, July, August, 1881.	18.6	0.16
June, July, August, 1882.	26.	0.18
July, August, 1883.	17.3	0.20
July, August, 1884.	21.8	0.13
July, August, 1885.	15.3	0.17
	For the five years, 19.8	For five years, 0.17

Modified Flap Operations (without iridectomy).

June, July, August, 1886.	13.75	0.39

From this, it appears that the average length of treatment in the later operations has been reduced from 19.8 days to 13.75 days, and that the resulting vision has been increased from $\frac{1.7}{100}$ to $\frac{3.9}{100}$. Of course, the number of cases here mentioned is too small to warrant our drawing any conclusion as to the general superiority of one form of operation over the other, and in the first series, no antiseptic was used, whereas, in the last, a partial antisepsis was tried. Yet, with this exception, the cases were all done under the same conditions, and by the same operator, and they are reported in the hope that other surgeons will give comparative figures which may throw some light on this interesting question. The details of the cases are appended:



EIGHT CASES OF EXTRACTION OF SENILE CATARACT BY A MODIFIED FLAP OPERATION.

No.	Sex. Age. Health.	Duration of Cataract. Functional Examination.	Operation. Convalescence. Duration of Treatment.	Vision.
1	Male. 72 years. Good.	4 years. Normal.	June 5, 1886. O. D. Normal operation and convalescence. Eye first opened on the seventh day. Parts in good position; wound well healed. Under atropine, the iris was found to be adherent to the capsule at several points. Pupil dilates irregularly. 14 days.	June 19, 1886. $\bar{c}+12.D.V. = 0.2$ July 17, 1886. $\bar{c}+10.D.V. = <0.5$ Aug. 18, 1886. $\bar{c}+10$ D.V. $= 0.8$ Reads Sn 0.5 $\bar{c}+13.D.$
2	Male. 41 years. Good.	3 years. Normal.	June 8, 1886. O. S. After the extraction was completed, a hernia of iris into the wound, which eserine would not reduce. Iridectomy followed by a small loss of semi-fluid vitreous. Eye first opened on seventh day. Parts well healed, and in good position. 12 days.	June 20, 1886. $\bar{c}+9.D.V. = 0.4$ July 22, 1886. $\bar{c}+10.D.V. = 04.$ Reads Sn 0.5 $\bar{c}+14.D.$
3	Female. 72 years. Fair.	Normal.	June 23, 1886. O. S. Normal operation and convalescence. 16 days.	July 9, 1886. $\bar{c}+11.D.V. = <0.2$ July 28, 1886. $\bar{c}+10.D.V. = 0.2$ Reads Sn. 1.25 with $+15.D.$
4	Male. 71 years. Good.	Normal.	July 17, 1886. O. S. After extraction, a tendency to prolapse of iris controlled by eserine. Eye first opened on sixth day. Wound well healed; central movable pupil. 12 days.	July 29, 1886. $\bar{c}+10.D.V. = 0.2$
5	Female. 62 years. Good.	Normal.	July 21, 1886. O. D. Operation normal. Eye first opened on sixth day. Pupil drawn a little upward by attachment of upper part of iris at periphery to the wound. Slight iritis. 20 days.	Aug. 10, 1886. $\bar{c}+11D.V. = 0.25$ Aug. 19, 1886. $\bar{c}+11D.V. = 0.3$
6	Male. 61 years. Good.	4 years. Normal.	August 1, 1886. O. S. Normal operation and convalescence. Eye first opened on sixth day. Wound well healed; parts in good position. Small amount of capsule in pupil. 12 days. February 16, 1887. Capsule has cleared from pupil.	Aug. 13, 1886. $\bar{c}+11.D.V. = <0.3$ Feb. 16, 1887. $\bar{c}+12.D.V. = 1$ Reads Sn. 0.5 with $+16.$
7	Male. 70 years. Good.	1 year.	August 4, 1886. O. S. Patient rather uncontrollable. After corneal cut was finished, patient contracted the muscles of eyeball, and forced out a small amount of semi fluid vitreous. Lens, at same time, displaced downward. Extracted with a scoop. Patient removed bandage on the third day, and appeared demented. Friends removed him on the tenth day, saying that he was often out of his head. 10 days.	Aug. 14, 1886. $\bar{c}+11.D.V. = 0.1$
8	Male. 55 yrs. (?) Poor.	6 years. No functional examination, as cannot communicate with patient, on account of absolute deafness and double cataract.	August 25, 1886. Operation normal. During afternoon after operation, took off his bandage several times, and refused to stay in bed. Cannot give him any directions, on account of his deafness. Twenty-four hours after the operation was up and dressed, with the bandage pushed to the top of his head. Wound entirely closed. Anterior chamber re-established, and some flakes of cortical floating in the pupil, and in front of the iris, at lower part of anterior chamber. No attempt was made to continue the bandage, on account of the uncontrollability of the patient. Convalescence normal. No re-opening of wound, no pain, very little redness of eyeball. Patient refused to stay in bed, and room was kept dimly lighted, to prevent his running into the furniture. When discharged, had some capsule in pupil. 14 days.	Sept. 8, 1886. $\bar{c}+10.D.V. = <0.1$ Sept. 15, 1886. $\bar{c}+10.D.V. = 0.1$

New Instruments.

A SIMPLE APPLIANCE FOR ROLLING GYPSUM BANDAGES.

BY HORACE G. WETHERILL, M.D., OF TRENTON, N. J.

IN the issue of the JOURNAL of April 28, 1887, there is a description of a simple box for rolling dry gypsum bandages, and as I have had in use for five years a very simple box devised by myself which has not been described and has the advantage of easy construction by any handy man with few tools in a few minutes, many of your readers will be able to make and operate it for themselves.

It is made from a cigar box of the usual size, and enough small rod iron or heavy wire to make two cranks and one guide for the bandage to roll over.

Holes were made in the box at A and A, B and B, C and C, and the guide is placed through those at B, in the lower corner of the box.

With a common screw (D) or screw eye the box is firmly screwed through its bottom to a board or table.

The bandage is then rolled on the crank placed through the holes A A, and after all is on that is desired or that the spindle will hold, the end of the bandage is led under the guide B B, and started on the crank placed through the holes C C, so that the crank may be turned in the direction indicated by the arrows.

Now plenty of plaster (the coarser the better) is put on the bandage between the guide-rod B and the spindle A A, and with the left hand on the roll at A A, to regulate the tension, the crank C C is started with the right hand; this carries the plaster down against the rod B B, which rubs the open meshes of the cloth full as the plaster is rolled over and over till all is taken up and more is needed. Plenty of plaster should be kept on the descending cloth, and it can be made to take up as much or as little plaster as the operator pleases, by regulating the speed of the bandage; all excess falls off as the bandage rises over the crank C C, if this is turned in the right direction.

I have made bandages with plaster in this way in my office with only a newspaper under the box to catch the droppings, for five years, as I said, with no dirt or flying plaster off the paper and only the plaster on my hands that came from taking the completed bandage off the spindle by a few reverse turns and pressure against the side of the box. My bandages are always satisfactory and set well, as I am careful in selecting good plaster, and use a very open scrim of only about twenty-eight or thirty threads to the inch.

I will gladly give any reader further information about this box if he will take the trouble to write me, as this sketch is hastily written and I am in doubt about its being perfectly clear, and will also be pleased to hear from any who find it of use, and a means of saving one of those little expenses we are so often called upon to meet.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

F. M. BUCKINGHAM, M.D., SECRETARY.

MAY, 1887, the President, DR. O. F. WADSWORTH, in the chair.

DR. C. H. WILLIAMS reported

A COMPARISON OF SOME CASES OF CATARACT OPERATION, WITH AND WITHOUT IRIDECTOMY.[1]

DR. WADSWORTH said that he thought Dr. Williams had emphasized too much the difference in the amount of sloughing in the old flap-operation and in Von Graefe's linear operation. If his memory served him, Von Graefe's own flap-operations, when compared with his own linear operations, showed by no means the difference in percentage of sloughing that Dr. Williams had stated as generally existing. Then the modern idea of sloughing is that it is an effect of sepsis, and this should be remembered when comparing the results of a method with antiseptic precautions with those of another method without antisepsis.

It is yet to be proved how far the new operation is to be trusted to give success with a round pupil. So far, all admit that prolapse of the iris, which cannot be replaced, occurs not very infrequently. If this happened at the time of operation, iridectomy may be done then; if it happen later, it is often impossible, even by iridectomy, to prevent the healing of the iris into the wound — a mischance of some moment. Again, the amount of vision possible with iridectomy is as good as can be expected with a round pupil. Dr. Wadsworth had more than once obtained vision better than one, by the modified Graefe operation.

The original operation of Von Graefe did go too far toward the ciliary region, and did sometimes excite sympathetic inflammation. As modified, it was less dangerous in this respect, but sympathetic inflammation had occurred with the earlier flap-operation, and will occasionally occur with any operation.

Dr. Wadsworth believed the new operation must still be considered *sub judice*. Dr. Gruening had stated that De Wecker himself performed iridectomy during the summer months, believing it to be safer.

DR. CHARLES F. FOLSOM read a paper on the

EARLY SYMPTOMS OF GENERAL PARALYSIS.[2]

DR. WEBBER said that the paper touches one of the most important points in mental medicine. He supposes that the early symptoms may be summed up as those of brain-tire. The intellectual part of the brain is tired, and its action is abnormal or defective. In making the diagnosis, attention must be paid to the past mental and medical history of the patient, and to slight changes of manner, such as can be observed only by the family and business associates, and to which they would pay no attention until warned by the physician. Thorough cross-questioning, on his part, is desirable, and diagnosis will be a matter needing great care. There may or may not be motor changes, but intellectual changes will never be absent, such as inability to carry on sustained reasoning, or to keep on doing the same thing. The more attention that is paid to this disease by physicians in general practice, so much the oftener will it be recognized in its early stage.

Any physician who meets with such cases must often act, if he means to do his duty by his patient, before he can make a sure diagnosis. The speaker does not believe it possible, during the early stage, to make a diagnosis beyond the chance of mistake. If the patient is treated and recovers, a certain class of authors will assume that there has been an error of diagnosis. The speaker wished to say nothing as to the treatment. It had been outlined by Dr. Folsom, and details must vary with the case.

DR. GOLDSMITH, present by invitation, said that he had been so unfortunate as to hear only the summing up of the paper. He referred to the great importance of early recognition of the disease. He does not know but that it must be a matter of theory whether cerebral exhaustion can ever be diagnosticated from general paralysis, or whether general paralysis is not a mere symptom of cerebral exhaustion. In many cases, the symptoms are very slight at first. We cannot be sure of paralysis until there are some paralytic, as well as mental symptoms present, and by that time, most observers are agreed that recovery does not take place.

He remarked that cerebral exhaustion is most likely to occur in persons of a neurasthenic type, and that general paralysis happens most often in those not of this type. If, therefore, in a given case, excellent business ability and common sense were recognized as part of the past history, he would be more suspicious of general paralysis than with the same symptoms in a neurasthenic patient. Dr. Goldsmith continued by saying that the study of the connection existing between syphilis and general paralysis is exceedingly interesting. His own opinion agrees with that of many others, that general paralysis is not a part of syphilis, but rather that it occurs where the nervous system has been deteriorated by previous syphilis, and thus the way has been prepared for it. It comes on long after the initial lesion, and has no post-mortem appearances characteristic of syphilis, in these respects offering an analogy to locomotor ataxia.

The connection between syphilis and the disease under consideration may be illustrated by cases like the following: A man had general paralysis six years after contracting syphilis, and his wife seven years after she received it. The wife's sister had a primary sore on the arm when sixteen years old, and had general paralysis eight years later. The argument is that three people in one family, one of them quite young, had one disease at a somewhat similar period, after having contracted the other. The speaker does not think he has seen much good result from iodide in the treatment, although he has nothing better to offer, and would use it if there were a history of recent syphilis, and the case were seen early. He thinks, however, that early recognition is important. Complete rest is an essential in the treatment.

DR. REYNOLDS inquired if the special senses become degenerated in the early stages.

DR. FOLSOM answered, that degeneration may begin anywhere. As a general thing, however, the special senses are not among the first to deteriorate.

DR. MINOT asked if there may be arrest in the progress of the disease without recovery.

DR. FOLSOM said that there can be no question of that.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, June 20, 1887.

DR. CHARLES A. LEALE read a paper on

THE PREVENTION OF CHRONIC DISEASE AMONG THE CHILDREN OF NEW YORK CITY,

in which he incidentally gave an account of the work of the St. John's Guild during the summer of 1886. For a number of years past, an appropriation has been made for the purpose of enabling the Health Department of the city to maintain a special corps of physicians to visit the tenement districts during the hot months of July and August; but no such special appropriation could be secured last year, and it was consequently necessary to abandon this service.

At a meeting of the Board of Managers of St. John's Guild, it was therefore determined to make an appropriation of their own funds for supplying this deficiency as far as possible; and three members of the board gratuitously volunteered to give up their summer vacations for this object, and devote the time to the furtherance of this new work. The members of the committee thus volunteering were Mr. John P. Faure, Secretary of the Guild, and Drs. B. V. Tompkins and C. A. Leale. Dr. Leale was chosen President, and in order to accomplish the most good, six physicians among those best fitted to perform the duties were chosen from a long list of those familiar with the English, French, German, Italian, Spanish and Hebrew languages, so that the greatest possible number of sick children might be benefited. The most densely-populated parts of the city were selected as those requiring most urgent attention, and they were divided into six districts; to each of which a physician was assigned.

This work began on the 3d of August, and ended on the 13th of September, and during this time 3,659 families were visited; representing 7,146 adults and 10,086 children. Among these there were found 217 sick adults, and 3,376 sick children. The most prevailing diseases were measles, diphtheria, scarlet fever, scrofula, and syphilis, and, in nearly every case these 3,376 children were not only without proper medical care, but were living in places rendering complete recovery to the large majority almost impossible. The vast importance of improving the sanitary conditions being therefore duly recognized, the summer corps of physicians were directed to make special investigations in regard to the sanitary condition of all visited, and, as a result, they reported that 699 premises were in good sanitary condition, 2,097 were in a fair sanitary condition, and that 863 families were surrounded by bad sanitary conditions or were living in illegal places unfit for human habitation. These were immediately reported to the Board of Health for correction.

To give the sick children the benefit of as much fresh air as was possible, 6,312 free tickets were distributed for the excursions of the St. John's Guild floating hospital, where they were given a sufficient quantity of food, and a hearty meal was furnished to their mothers. To twenty-four very sick children were given tickets admitting them and their guardians for a week or two at the hospital at Cedar Grove, Staten Island, where it was found they were greatly benefited. The very large number of children left with organic heart disease, following scarlet fever, was particularly noticed.

During the entire service the summer corps of physicians devoted, on an average, four hours daily to their work, and one evening of the week they met, together with the members of the supervising committee mentioned, to report verbally the results of their observations, compare notes, and seek counsel in difficult cases. All cases of special importance were referred to the committee for investigation and consultation. Some of these were of such character as required prompt action for the protection of themselves and neighbors. A little girl was found to be suffering from syphilitic ulceration of both eyes, and otherwise poisoned, as the result of a rape. When visited she was found living in two rooms with her father, mother and grandmother, all of whom were in such a drunken condition as to render them completely helpless. Another child, a boy, was found selling fish while his fingers, mouth and some other parts were in an ulcerating syphilitic condition. He had contracted the disease in a neighboring city, and, returning to his home, gave it to his grandmother, mother, and two sisters, and to two infants beside.

At the termination of the service final reports were made by the visiting physicians. One of them wrote; "The cause of the great death-rate among children under five years of age I found to be attributable to over-crowding filth, filthy habits, and bad drainage. Upon a hot summer's day to enter a room in a rear house, whose walls were cracked and besmeared with refuse, and perhaps dead vermin, occupied by a family of six or eight, harboring three or four boarders, upon the floor of which might be seen soiled linen, particles of food and children with a mother standing about the red-hot stove, washing and cooking, and perhaps attending to a sick child, lying in a dark bedroom, suffering from cholera infantum, diphtheria, or scarlet or typhoid fever, was a spectacle frequently indeed brought to my attention." The greater portion of this physician's district was inhabited by Hebrews who had lately emigrated from Austria, Hungary, Poland, Roumania, and Prussia.

Another, whose district also lay in a region densely crowded with a foreign population, wrote: "I noticed a great number of cases of diseases of the eye and ear among the younger children, and these diseases I found to be particularly prevalent among those that were subjected to especially bad hygienic influences. All the houses, without any exception, are overcrowded, and are in a frightfully filthy condition; the rear houses, in addition, being dark and badly ventilated. Here you find as many as twelve to fourteen people occupying one apartment — this apartment consisting, as a rule, of three rooms. In some of these apartments you find the father, mother and grown-up sons and daughters all sleeping, you might say, in one room, without any regard for delicacy or decency. The mortality among the very young children in these houses is of the very highest percentage. If they are overtaken by sickness, their vitality being in such a low state, it almost always results fatally unless they can be removed to some locality where fresh air can be obtained. Even one excursion on the salt water, or in the country, will act like a charm in some cases; the results being better than could be secured with any medicine. The cases that are especially benefited are general debility and marasmus."

A third physician wrote: "From what I learned during the few weeks I had for observation, I am con-

vinced that, to the children of the poorer classes, the Floating Hospital has proved an inestimable boon, not only in affording relief to those suffering from acute disease, but in fortifying others against the terrible effects of over-crowding and bad ventilation. At the request of Secretary Faure, I inspected the Seaside Nursery on Staten Island, and was much pleased with that institution, where I found everything provided for the comfort of those requiring hospital treatment and fresh sea-air. . . . In the small yard of a rear tenement, groups of sickly children were seen playing around an almost open cess-pool, a so-called 'school-sink.' These children have characteristic appearances; they are stunted in growth, pale, and, as a rule, have some form of ophthalmia. Rheumatism is also a frequent visitor to these miserable abodes, and leaves, in many of those who survive, some form of heart disease. Out of more than thirty children found in one of these small yards, only one could be said to be in vigorous health."

During the month of December, the Board of Trustees of St. John's Guild, desiring to obtain further information in regard to the sanitary condition of the places visited by the special summer corps of physicians, made a request that a re-inspection of the worst places should be made, and Dr. Leale gave the following as a sample of the reports received from the physicians: "Not often have I been so agreeably disappointed as I was last Friday and Saturday, when I re-visited the 'pest-holes' which have been changed to human dwellings. While there is still room for improvement, it shows what can be done to better the condition of the poor. I firmly believe the work done by the Guild during the last two weeks exceeded that of the entire season, for 'an ounce of prevention is worth a pound of cure,' and your noble institution surely prevented a vast amount of sickness by its attention to sanitary inspection."

Dr. Leale then went on to say: Such was a portion of the reports that I made to the Trustees of an institution, which had over a quarter-of-a-million of sick and crippled children under its care, and which, with its unique opportunities, had probably done more than any other to prevent disease among children. No child is received without a physician's certificate, stating that the child is sick, and naming the affection from which it is suffering (excluding all those of a contagious character); and this certificate entitles the bearer either to the benefits of our Floating Hospital, which feeds and takes the children, with their mothers, on daily excursions to the ocean during the heated term, or to a permit for a stay of two weeks at our Seaside Nursery, which has an ocean beach on one side, and a beautiful grove of shade-trees on the other. It is unnecessary to ask what such work does towards the prevention of disease and premature death, as a single visit will demonstrate its usefulness. At one of my visits, there were over thirteen hundred sick children with their guardians, on one of the daily excursions, and I saw numbers under five years of age with chronic diseases. There were many epileptics, idiots, and deformed. Several had curvature of the spine or hip-joint disease, bow-legs or club-foot, while tuberculosis, syphilis, and scrofula claimed a large share. The great number of cases of neglected eye, ear, and throat diseases, also, only too plainly told the story of the necessity of prevention, in early life, of permanent disability.

Dr. George T. Harrison read a paper on the

INDICATIONS FOR THE INDUCTION OF PREMATURE LABOR.

In general terms, he said it might be stated that the object we seek to attain in the induction of premature labor was to give a better prognosis in those cases in which the further continuance of pregnancy, or childbirth at term, involves great dangers to mother or child, or both, by an artificial interruption of pregnancy at a time when the fœtus is capable of maintaining existence outside of the uterus. As the chief danger to the mother in the performance of this operation did not lie, as was formerly supposed, in the mechanical irritation of the uterus, but in septic infection, it could confidently be affirmed that if proper antiseptic precautions were observed, this danger was an avoidable one.

The first and most important indication for the induction of premature labor was undoubtedly furnished by pelvic deformity of a moderate degree. Theoretically, this indication was clear enough, but in practice, a number of difficulties might arise in its fulfilment. In the first place, the means for pelvic measurement at our command were by no means as perfect, as they only enabled us to attain to an approximation to correctness. In the next place, the exact period of gestation might be exceedingly difficult to decide in certain cases somewhat deviating from the normal. Irregularities were especially prone to occur in cases of contracted pelvis, from the fact that the head was prevented from entering the pelvic cavity, and thus certain signs of pregnancy were modified.

Having fixed the date of gestation as accurately as possible, the next question was to decide in what week of pregnancy the induction of premature labor was indicated. The earlier the labor was induced, so much the less danger of injury to the soft parts of the mother, and so much greater the chances that the child would be born alive; but, at the same time, the prospect of the child's continuing its existence diminished in proportion to its prematurity. On the contrary, the later the labor was induced, the greater the danger to the mother and child, but the better the prognosis for the preservation of the life of the latter, if it come into the world living. The problem we had to solve, then, was to choose such a time when the child could traverse the pelvis without injury to itself or the mother. In order to do this, it was necessary to form an accurate idea of the size of the pelvis and of the child's head.

In the flat pelvis, the kind of deformity most frequently met with in practice, we had simply to ascertain the measurement of the conjugate diameter. In the case of the equally contracted pelvis the problem was much more intricate. Here it was necessary to introduce the entire hand into the vagina in order to form an idea of the pelvic cavity, and errors were often likely to be made, notwithstanding every precaution to the contrary. The determination of the size of the child's head also presented many difficulties. Schroeder ascertained from careful measurements of the heads of sixty-eight prematurely born children that the head was larger from the twenty-eighth to the fortieth week of utero-gestation than was generally supposed to be the case. It must, however, be borne in mind, Dr. Harrison said, that the heads of immature children are more easily moulded and much

more compressible than obtained in the case of the head of the child at term.

Other criteria which might serve as a guide were the facts, based upon experience, that large and powerful women give birth to large children, and that the weight of the child increases with the age of the mother and with the number of preceding births. The transverse diameter of the heads of the children of young primiparæ was relatively small, while the contrary was true in those multiparæ who were comparatively old. The method proposed by Frankenhäuser and Roth, of determining the relation between the head of the fœtus and the pelvis of the mother, he thought worthy of trial. This method consisted in pressing the child's head into the pelvis, and, by means of the fingers in the vagina, ascertaining if it were possible for the head to descend below the brim. According to Frankenhäuser, this examination should be repeated every eight days, and operative interference should only be resorted to when the descent of the head below the brim seems no longer possible.

As to the degree of pelvic contraction which justifies a resort to the induction of premature labor, Dr. Harrison believed that in the simple flat pelvis a conjugate diameter of seven and one-half centimeters, or seven centimetres in very exceptional circumstances, should be the extreme limit. In the case of the equally contracted pelvis, when the shortest diameter was at least eight centimetres, it might be affirmed that the operation was justifiable. As a rule, the thirty-sixth week was to be selected, and only exceptionally should the term of gestation be anticipated by operating in the thirty-fourth week.

Secondly, an indication for inducing premature labor was given by certain severe diseases which endanger the mother's life and are amenable to no other treatment, while, on the other hand, either a disappearance or at all events an amelioration of the symptoms may confidently be expected with the termination of the pregnancy. One of the most interesting diseases coming under this category was uncontrollable vomiting appearing late in pregnancy. Occasionally it threatened such dangers that operative interference was imperatively demanded, and such a case, which he had recently seen in consultation, Dr. Harrison narrated. In this instance, however, premature labor began spontaneously before artificial measures for bringing it on had been taken.

Another disease of paramount importance which might indicate this operation was nephritis; although it was important that a distinction should be made between those cases in which the anatomical and functional disturbances of the kidneys are evolved by the state of pregnancy, and those in which the disease is an interstitial or parenchymatous nephritis which either existed prior to conception or has been produced during the course of the gestation. As to the induction of premature labor to ward off attacks of eclampsia, this, as was well known, had been a fertile source of controversy; but Dr. Harrison believed that the indication was clear and decided when the urine shows a constantly increasing quantity of albumen and cells in a state of fatty degeneration, and when all the therapeutical resources at the command of the physician have proved unavailing. Again, an excessive degree of œdema and transudation with the serous cavities might demand the performance of this operation.

To make the differential diagnosis between the two forms of nephritis mentioned, which had been termed *nephritis gravidarum* and *nephritis in gravitate*, was no easy task. The clinical phenomena are so nearly alike that the previous history of the case and the course could alone decide as to which form was present in any given case. It was abundantly demonstrated by numerous observations that in chronic nephritis in pregnant women there was a great tendency to abortion and premature labor, and not so much to attacks of eclampsia.

A third indication of premature labor, in the interest of the child, is met with in certain cases in which former experience has shown that the children die at a certain date of gestation, when this time is not far removed from the end of pregnancy. Some cases of nephritis gravidarum came under this category. If syphilis was the cause of the death of the fœtus the artificial interruption of pregnancy, Dr. Harrison thought, was contraindicated; for, in the first place, he said, according to Kassowitz, in latent syphilis of the father or mother, the death of the fœtus took place in each ensuing pregnancy somewhat later, so that in successive pregnancies there came into the world first abortive fruits, then immature macerated, then prematurely born macerated, and finally mature, but diseased, children; still later mature healthy children. On the other hand, we gained nothing by the artificial interruption of pregnancy before the expected time of the death of the fœtus; for the child was already diseased, and might be considered as lost.

In cases, however, in which chlorosis or other anæmia of the mother, or change in the umbilical cord or placenta, had caused the death of the fœtus, the indication of premature labor before the time which experience had shown to be the critical period might be the means of bringing a living child into the world.

It was rare that diseases of the heart or lungs gave an indication for this operation, though they occasionally did. Lastly, an indication for the anticipation of the term of gestation was furnished by those dangerous and incurable diseases of the mother which would probably cause death before the end of pregnancy, in order to avoid the performance of the Cæsarean section post mortem, or in articulo mortis.

In the discussion which followed the reading of the paper, Dr. Leale expressed the opinion that in syphilitic cases it was sometimes desirable to induce premature labor, since by this means a living child might be brought into the world, which, although diseased, might be restored to health under appropriate treatment, but which, if left to the course of nature, would inevitably be still-born. By this means a living child might be gained in the series of Kassowitz referred to by Dr. Harrison.

DR. H. M. BIGGS presented, on behalf of Deputy Coroner Jenkins the specimens from a case of

RUPTURED AORTIC ANEURISM,

the rupture taking place at the junction of the transverse with the ascending arch of the aorta, and entering the left lung. There were also evidences of acute endarteriitis of the aorta, and of the beginning of a small aneurism near the orifice of the right innominate artery.

DR. C. S. WOOD then referred to a somewhat similar case which had occurred in his own practice, the specimens of which he had presented at a meeting of a sister society.

Recent Literature.

Medical Electricity: A Practical Treatise on the Applications of Electricity to Medicine and Surgery. By Roberts Bartholow, A.M., M.D., LL.D. Third edition, enlarged and improved, with 110 illustrations. 8vo. pp. xxiv, 304. Philadelphia: Lea Brothers & Co. 1887.

The fact that the volume before us has reached a third edition is evidence of the favor with which it has been received. Though distinctly inferior, as a scientific treatise, to the works of De Watteville and Erb, it nevertheless is a useful and trustworthy practical manual. The present edition has been fully revised, and has taken note of many of the recent contributions to electro-therapeutics, especially in the domain of surgery, but we regret that the author has not dealt with the question of density in the application of galvanism, or given his voice in favor of Erb's electrodes, which are now adopted as the standard.

A Manual of Obstetrics. By A. F. A. King, A.M., M.D. Third edition; 12mo, 379 pages. Philadelphia: Lea Brothers & Co. 1886.

With commendable zeal the author in preparing this edition has striven to keep pace with the recent advances in obstetric science. Some portions of the book have been rewritten, and every chapter bears evidence of careful revision: there are forty-one additional pages. The value of the work is much enhanced by the new illustrations, forty-three in number, and by the more extensive use of paragraph headings.

Altogether the book is a very good one; and while we have in no way changed our opinion of manuals, as expressed in our notice of the second edition of this book, we would much prefer that a student should *master* a manual like this one than that he should have only a vague and indifferent knowledge of one of the larger treatises.

Transactions of the American Gynecological Society. Vol. II. New York: D. Appleton & Co. 1887.

These yearly volumes are noteworthy as presenting from time to time the results of the thought and experience of the most distinguished men in this branch of the profession in America. As such they claim our attention, and challenge our criticism. While the individual papers differ in merit, there are always some which from their originality deserve especial notice. As in all branches of science, so in gynecology, there are always certain subjects which are in the stage of trial, which are the burning questions of the day, and which more than any others are being talked about, written about, and tested in practice.

Such subjects have always had a prominent place in these transactions, and the present volume is no exception to the rule. The most notable papers in the sense above indicated, are three which discuss the uses of electricity in its various forms in gynecology. Dr. Engelmann, in a very elaborate paper, gives in minute detail the methods and uses of the different electric currents, describes the various instruments, and enumerates the different affections in which this agent has been tried, with the rules for its employment. The paper has its chief value in the precise rules it gives for the kind, strength, direction and intensity of the current to be used, instead of the vague general directions which have almost uniformly been the rule before. According to Engelmann, the range of diseases in which it may be advantageously employed is very large, and the chief criticism we would make is, that the author has conceived the scope of its application to be wider than future experience will show is warranted.

Two papers on special uses of this agent emphasize the growing importance of electricity in the therapeutics of gynecology. One is on the "Treatment of Procidentia by the Galvano-cautery," by Dr. John Byrne, the other on "Electrolysis in Gynecological Surgery," by Dr. Wm. H. Baker. The latter paper deals principally with its employment in cases of fibroids, thirteen out of fourteen cases of which were relieved of suffering and somewhat diminished in size.

Anything which Dr. T. A. Emmet has to say is worthy of attention, and in the paper which he has contributed to this volume on "Pelvic Inflammation," there are a few points which deserve notice. He has been surprised to find that cases where he has diagnosticated "thickening of the broad ligaments," and which later have been operated on for the removal of diseased Fallopian tubes, have shown little evidence of previous attacks of cellulitis. This he explains by presupposing in all cases of inflammation of the tube except those of gonorrhœal origin, a cellulitis, which by absorption and contraction of the tissues after the active stage is over, has drawn up the vaginal wall, and drawn down the tube until they are very nearly in apposition. The broad ligament is somewhat flattened out, but not thickened, and the bloodvessels which have lost their support, and from long-continued obstruction to the circulation become distended, are what are felt as a "thickening of the broad ligament" itself. As the veins become partly emptied after death, this condition may easily be overlooked.

Dr. Englemann enters his protest against the indiscriminate removal of tubes, even when diseased, and feels sure that prolonged local treatment will, in many instances, be followed by a complete cure.

Other notable papers are, "The Influence of Maternal Impressions on the Fœtus," by Dr. Fordyce Barker, in which he argues in favor of the positive influence of such impressions on the child in utero; and "The Value of the Blueish Coloration of the Vaginal Entrance as a sign of Pregnancy," by Dr. J. R. Chadwick, where for the first time the subject has been investigated clinically, and definite facts with regard to it established by statistics. These facts are: I, That its absence is not to be accepted as evidence that pregnancy does not exist, especially in the first three months, when satisfactory evidence is most needed; and, II, That from (and including), the second month this color is generally present, and often of such character as to be diagnostic.

The other papers in the volume will well repay perusal, and as a whole, compares favorably with its predecessors.

— At a recent meeting of the Berlin Medical Society, Professor Virchow announced that Dom Da Costa Alvarenda, a Portugese physician, had, to show the esteem in which he held German medical science, bequeathed a sum of about £3000 to the Society; the same testator is reported to have left a similar sum to the Philadelphia College of Physicians, of which he was an honorary member.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 1, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

PARATRIPTICS.

THERE is a clumsy Greek word which means literally to *strike or rub against*. It has lately been proposed to strain a figurative meaning out of this word (which has not yet risen to the dignity of a place in standard medical lexicography), and apply it to that class of nerve-modifiers which are believed to be restrainers of organic waste: tea, coffee, tobacco, wine, coca, etc. It is generally admitted that these substances do, to some extent, limit nervous and muscular expenditure, but their mode of action is largely a matter of conjecture. Nor is it perfectly clear how, in restricting tissue-waste, they can be force-givers (*dynamophorous* was the euphonious word coined by Gubler to express this property). Liebig, we believe it was, who first advanced the explanation that such substances as alcohol supply force to the economy by being themselves consumed, instead of the tissue-elements. Later researches seemed to throw doubt on this hypothesis, although the best authorities seem now agreed, as a result of rigid experimentation, that, at least, one of these "paratriptics," alcohol, in part undergoes transformation in the organism, yielding up force.

Whatever may be the true explanation of the *modus operandi* of these agents, it is none the less a matter of common experience that, under certain circumstances, and within certain limits, they act the part of food, making the ingestion of less food necessary, and facilitating the performance of work. This seems to be emphatically true of coca, the leaf of which is to the Indian of the mountains "the delight, the support, and in some measure, the necessity of his life." Certainly, if there be any one thing which has impressed travellers in Bolivia and Peru, it is the immense amount of work which the natives can accomplish on the most meagre alimentary rations, when supplemented by a supply of their favorite coca.

With regard to tobacco, which Von Bibra calls the "universal stimulant," this narcotic being used by 800,000,000 of the human race, we are not prepared to endorse all that has been said in its praise, nor do we think that this "weed" has been deserving of all the opprobium that has been heaped upon it from King James's anti-tobacco tirade to the present time. Certain it is that, while many are harmed by it, many, on the other hand, affirm that it is a "lightener of labor, and a facilitator of thought." In this connection, it is interesting to read what a high literary authority, who is, by the way, not a physiologist, says of the benefits which, we suppose, that he has personally experienced from the occasional pipe or cigar.[1] The citation is a curious one, as an attempt to explain on physiological principles an action which is common to all the so-called "paratriptics" — an explanation anticipated by Anstie:

"What do we do to ourselves when we smoke? In the first place, we stimulate or increase the normal molecular activity of the sympathetic system of nerves. By so doing, we slightly increase the secretion of saliva and of the gastric, pancreatic, and intestinal juices. We accomplish these all-important secretory actions with a smaller discharge of nerve-force. We economize nerve-force in digestion, and by this we mean to say that we perform the work of digesting food just as well as before, and still have more of the coördinating and controlling nerve-power left with which to perform the other functions of life. Thus, at the outset, tobacco exhibits itself as an *economizer of life*. Such is the inevitable inference from its stimulant action on the sympathetic."

The conclusions[2] reached by a well-known medical authority, who has made personal researches on this subject, are as follows: "Tobacco, when the food is sufficient to preserve the weight of the body, increases that weight; and when the food is insufficient, and the body, in consequence, loses weight, tobacco restrains that loss."

It would be easy to pursue the subject, and show that similar results and conclusions have attended researches and experiments undertaken to ascertain the physiological effects of tea, coffee, and alcohol.

The author of the article on "Sedentary Men and Stimulants," in the *North American Review* for August, 1887, discusses with much good sense the action of paratriptics in their relation to the conditions of the laboring and sedentary man. The former wastes his muscles out of all proportion to his brain, while the latter does the exact reverse, and both thus destroy the relations which should exist between their food and necessary repair. Both must eat the same food, and each is compelled to swallow more than he needs for one portion of the body, in order that he may obtain sufficient nourishment for another. The writer goes on to show that, while the laboring man can stand this by virtue of the muscular labor which he performs, the sedentary man, to nourish his overtaxed brain, must eat too largely and too abundantly for the unemployed portion of his body. Hence "dyspepsia"

[1] John Fiske. Tobacco and Alcohol. New York: Leopoldt & Holt.
[2] W. A. Hammond. Physiological Effects of Alcohol and Tobacco. American Journal Medical Sciences, Vol. 22, p. 319.

and "biliousness" result. "It is certain," he says, "that sedentary men (unless their appetites are restricted) are quite as heavy eaters as laborers, and rarely escape the disorders mentioned. The exceptions comprise chiefly those who, 'by the habitual use of the so-called paratriptics — tea, coffee, tobacco, wine, etc. — daily lessen the waste of the brain, and thus diminish the amount of necessary food.'"

The article concludes with a tirade upon what the writer calls "*the greatest gastronomic sin of the times, an indulgence in all forms of freshly-baked bread*," whose suppression "would cause biliousness and dyspepsia largely to cease to afflict sedentary men;" and with the remark that, of all the paratriptics, "it may finally be said that only personal trial or skilled advice can determine which is best suited to each individual."

We cannot forbear expressing the opinion that Dr. Searle's fresh-bread theory of the causation of dyspepsia and biliousness is rather crude; there are too many exceptions to admit of its being received as a general law. At the same time, it is probably true that it is the excess of foods of all kinds, which are consumed above the needs of the system, or its ability to appropriate them, which is the principal factor in the production of those complaints.

The statement, moreover, that sedentary men eat as much food as laboring men who perform exhaustive muscular toil must be taken with grave reservations. It will, we feel sure, when examined in the light of experience and careful statistics, be found to be wanting in fact.

THE ABUSES AT THE WARD'S ISLAND INSANE ASYLUM.

THE Standing Committee on the Insane of the New York State Board of Charities, consisting of Dr. John J. Milhau and Messrs. Craig and Foster, having made a thorough examination of the three thousand folios of testimony taken during their investigation in July, have now presented their report in regard to the existing abuses at the City Insane Asylum on Ward's Island. The Medical Staff, we are glad to observe, is in no way involved in the general condemnation of existing conditions.

While the cost of food and maintenance, including clothing and care, is extremely low for this class of individuals — amounting to less than thirty-three cents per capita a day — the Committee is unable to find, on the whole, any deficiency in the quality of the food supplied as compared with the purchase or the market price thereof, or bad faith or gross negligence on the part of the Board of Charities and Correction, whose business it is to furnish such supplies. As to the improper character of the food itself, the testimony is cumulative and undisputed, and proves conclusively that the dietary is insufficient in variety and nutritious qualities. It is also shown that with the exception of one article — the bread, which is fairly satisfactory — the cooking is bad, and necessarily so, because of the inadequate appliances in a kitchen intended for 500 to supply the wants of over 1,700 patients, besides attendants. The Committee, therefore, find that "this condition of things is wrong and shameful; especially does it so appear in view of the fact that those who are compelled to eat the mixtures set before them are sick persons requiring a wholesome diet."

The unwise economy which is evident in the food supplied to the institution is exhibited in its buildings. The asylum building proper has a capacity of 1,000 patients; but the population at the time of the investigation was nearly 2,000; while the annex on Ward's Island, and the branch on Randall's Island, ought in the opinion of the Committee to be condemned as uninhabitable. In speaking of the evils produced by overcrowding, the Committee say: "It is not difficult to imagine the general condition, with patients huddled together, many of them without sufficient air space, in associate domitories, and most of them deprived of day rooms, which have been filled with beds, and confined to long wards as cheerless and comfortless as are these miserable masses of humanity which crowd them. The day attendants, compelled to pass fifteen working hours in these repulsive places and in the arduous duties of restraining and quieting the excitements which are responsive to such environments, are at night compelled to sleep two or three and six or seven in small and uncomfortable rooms. In this condition violent wards must become more disturbed, and filthy wards more demoralized, even with the best material for educated attendants. But the worst effect is that, while the salaries of these officers are not relatively low, the general situation repels not only the best, but even ordinarily good men, who would otherwise become applicants for their position, and attracts such as have no due appreciation, and perhaps not even a dull apprehension, of the depressing and disturbing influences to be overcome."

In regard to the treatment by the attendants, the circumstantial evidence received was such as to show beyond all doubt that there are numerous and continual injuries and indignities inflicted upon the patients by the attendants. Overworked, irritable, and ignorant attendants, who need the constant direction and discipline of persons other than themselves, and whose antecedent experiences have never resulted in self-restraint, are placed in positions of absolute and exclusive control of badly crowded and excited patients, without appeal or remedy except on unverified reports to absent medical authorities. The presumption that offences are continually practised by such attendants upon patients in such conditions is of the highest degree of probability. "This moral certainty of abuses abounding in the wards of this asylum," the report goes on to say, "is, if possible, further established by evidence amounting to almost mathematical demonstration. . . . Comparison shows that only a small proportion of such acts of personal violence committed

by attendants on patients, which are not witnessed by any member of the medical staff, are ever reported and proved to the satisfaction of the medical authorities."

In the matter of medical treatment the Committee quote the opinion of Drs. Trautman and Macdonald, that proper distinction had not and could not be made in favor of the treatment of the acute insane, and that not even proper care and attention had been or could be given to the chronic insane.

In closing their report, the Committee say: "The facts proved show that the abuses which have been continued, and against perpetual protests, endured, in the New York City Asylum for the Insane are the effects of permanent causes. The difficulties which have hitherto resisted all efforts for the removal of these causes will not yield to attempts of reform on the surface of the affairs or administration of this asylum, for these causes are, as we have seen, general and inherent in the Department of Charities and Correction, or in the Department of Estimate and Apportionment, or are resultants of lines of error in the relations of the two departments."

For provisional relief, the following immediate remedies are demanded and proposed:

(1) The Board of Charities and Correction to give to the Board of Estimate and Apportionment plans and specifications for all buildings and improvements, in respect of which special appropriations are asked or needed, and also annual accounts and reports, and all necessary information for the general appropriations.

(2) The Board of Estimate and Apportionment to transfer a certain residue of $50,000, and to make further special appropriations, such as may be necessary for proper buildings and improvements on the farm at Central Islip, Long Island, and to make sufficient apportionment for temporary buildings and accommodations, as well as for the current expenses of the institution.

(3) The Board of Charities and Correction diligently to push forward the necessary preparations for the transfer of patients to the farm. The buildings for the accommodation of such patients to be on the cottage plan, none to exceed two stories in height, and all to be inexpensive and in accordance with principles illustrated by the Alt Sherbitz Asylum in Saxony.

(4) The Board of Charities and Correction to reform, as far as possible, the various abuses pointed out as now existing in the Ward's Island Asylum, and to provide adequate, healthy, and cheerful rooms for all patients and attendants; to institute schools for the patients, and training schools for the attendants, both of which have been found successful experiments in the State insane asylums; and to give increased facilities for healthful and productive labor of the patients on the farm and otherwise.

(5) The Board of Charities and Correction, so soon as the new conditions and environment hoped for make it possible, to provide for the treatment of the acute insane, separate from the care of the chronic insane, under the advice of the General Superintendent of both city asylums, and of the State Commissioner in Lunacy.

In order to secure permanency in the reforms thus suggested, the Committee recommend:

(1) Either the management and government of both the insane asylums (on Ward's and Blackwell's Islands), with all their various branches, to be given to a Board of Trustees composed of men and women appointed by the Mayor, to whom they should report; or, as the alternative preferred, all matters referring to the insane to be intrusted to one independent Commissioner, appointed by, and responsible to, the Mayor. If this plan were carried out, the Department of Charities and Correction would have to be reorganized, and might well be divided into four separate departments, each with an individual head, respectively, for (1) insane asylums; (2) institutions for children; (3) all the hospitals and the almshouse; and (4) the workhouse, the several city prisons, and the penitentiary.

(2) On the omission of the city to provide such permanent, as well as provisional relief, the State to intervene in accordance with the existing laws relative to the care of the insane within its borders. The Willard Asylum Act, passed in 1865, which requires counties to send their insane to State institutions, does not except the counties of New York and Kings, but, as no provision for the insane of these counties has thus far been made in the six State institutions, the powers of the State Board of Charities under this act and supplemental acts have heretofore been practically inoperative in the counties in question.

LAPAROTOMY FOR PELVIC PERITONITIS AND SALPINGITIS.

THE paper on "Laparotomy for Pus in the Abdominal Cavity and for Peritonitis," read at the recent meeting of the Massachusetts Medical Society, and published in the issue of the JOURNAL for August 18th, was of value and interest as indicating the future possibilities of cure in diseases formerly regarded as beyond the reach of surgery and medicine, and the conclusions of Dr. Irish have received striking confirmation by four cases lately reported by Terrillon to the Academy of Medicine, Paris.

One of these patients was a young woman, aged twenty years, pale and weakly. This woman had her first child at the age of sixteen and a half years, and the second, two years later. From the first confinement she made a good recovery, the second was followed by a smart attack of pelvic peritonitis. An imperfect convalescence followed; then the patient suffered from exhaustive metrorrhagias, continuous pains in the abdomen, and inflammatory recrudescences from time to time. Laparotomy was performed May 21, 1887, and on the right side Terrillon removed an impervious Fallopian tube of large size, full of muco-pus,

with a diminutive nodulated ovary containing a small abscess; all adherent to the peritoneum. The Fallopian tube on the left side, which was also removed, was similar to the right, and the right ovary, as large as a hen's egg was transformed into a blood cyst.

At the time of the report (May 31st) the patient was regarded as out of danger, and rapidly convalescing.

Another patient had been for seven years suffering from salpingitis and peritonitis. Both Fallopian tubes with ovaries were removed; they were enormously thickened and dilated, full of blood clots, impervious and adherent to the ovaries by false membranes. The operation was followed by restoration to health and cessation of the metrorrhagia. The other two cases (the last of which was treated by laparotomy in March), were similar in kind to the one just mentioned.

Terrillon, in commenting on these observations called attention to the probable origin of the peritoneal inflammations accompanying these cases, and his view strikingly coincides with that of one of the speakers at the Massachusetts Medical Society Meeting, respecting the extension from some inflamed mucous surface of the localized peritoneal inflammation: "There exists," he says, "an inflammation of the mucous membrane of the tubes. According to the clinical characters and the lesions observed, this inflammation seems to have begun in the uterine mucosa. It invades the mucosa of the Fallopian tube, overflows the tube (so to speak) by its fibrinated extremity and spreads over the adjoining peritoneum and ovary. A localized peritonitis thus results. These lesions account for the pain and peritoneal accidents of the onset, the hæmorrhages of the mucous membrane of the uterus and Fallopian tubes, whose vascularity is augmented, the sufferings referred to the region of the ovaries and lower part of the abdomen, and the disorders of the nervous system and digestive tube accompanying. They also account for the persistence of the functional disturbances, despite the means employed to ameliorate them, and the necessity of radical surgical interference which alone can effect a cure."

MEDICAL NOTES.

— The *Revue d'Anthropologie* gives the number of centenarians dying in France of late years as follows: in 1879, 38; in 1880, 31; in 1881, 38; in 1882, 44; in 1883, 51.

— Dr. Charles G. Stockton, of Buffalo, has been elected to succeed the late Dr. Thomas F. Rochester as Professor of Practice of Medicine and Clinical Medicine in the medical faculty of the University of Buffalo.

— Cable dispatches to the daily press report the death from hydrophobia of Viscount Doneraile, of the Irish peerage, who was attacked by hydrophobia, resulting from the bite of a fox received last January. Lord Doneraile was bitten on the hand by a tame fox, a vixen, which he kept as a pet. The coachman, who came to his assistance, was also badly bitten, on the leg as well as on the hand. At the time Lord Doneraile thought that the fox was only out of temper, as it did not appear out of health. As a precaution, however, the animal was shut up, and on the third day it was found dead. A veterinary surgeon examined the body and pronounced the attack a case of rabies. Lord Doneraile started immediately for Paris, taking the coachman with him, for treatment by Dr. Pasteur. Thus, within five days of being bitten, the two patients were in Pasteur's hands. The fate of the coachman is not stated. We await with interest further and more authentic details of the case.

— Drs. Cyrus Edson and Willard Parker, of New York, having differed in their opinions as expressed in articles written for the *Epoch*, on the point of what color is best for summer clothing, and Dr. Edson having said that dark clothes are best because black radiates heat more freely than white, and having cited the polar bear as best adapted by color to hold the bodily heat, the *Sanitary Engineer* says that Dr. Parker is right and Dr. Edson is wrong. The experiments of Coulier (*Expériences sur les étoffes qui servent à confectionner les vêtements Militaires.—Jour. de la Physiologie*, 1858), show that the difference of absorption and radiation between different colors of the same stuff are not perceptible in the shade at temperatures between 70° and 100° F., while the white is much less absorbent than the black when exposed to the rays of the sun. Hence the common opinion which favors light clothing for hot weather is right.

— The *St. Louis Medical and Surgical Journal* referring to the lately published letters of Wagner, the composer, written from the court of the late King of Bavaria, says that they show clearly a state of inverted sexual instinct on the part of the musician in his relations with the mad king. Wagner spent much time and description over the designing of gorgeous female toilettes which he wore in the presence of the king. In the letters the writer enters into all the petty minutiæ concerning the material, cut and trimming of the various garments which go to make up female finery, from the lace chemise and dainty hose to *décolleté* corsages and trailing robes.

— The Spanish Society of Hygiene invite essays suitable for publication in the form of pamphlets or tracts, on the following topics: 1. The Hygiene of Work in Second Childhood. 2. Methods of obviating the Evil Effects produced on the Sight by faulty Conditions of Schools, and the Methods of Instruction. A prize of $50 will be given for the best essay on each subject. Foreigners may compete, and the essays may be written in Spanish, French, Italian, Portuguese, or Latin. The length should be that of a sixteen-page pamphlet. The MSS. must not be signed, but must bear a motto, and accompanied by a sealed envelope bearing the same motto outside, and containing the name of the writer within. The essays

must be addressed to "La Sociedad de Higiene, Montera No. 22, Madrid, before September 30, 1887. The awards will be announced at the opening of the academical session.

Miscellany.

HYGIENE IN FRENCH SCHOOLS.

THE Paris correspondent of the *Lancet*, writing under date of August 9th, says: "The Academy of Medicine has, to-day, been occupied in the discussion of the conclusions come to by a Committee appointed to report on intellectual overwork in schools and other places of education. After considerable discussion, in which MM. Lagenan, Trélat, Hardy, and Brouardel joined, the following conclusions were adopted: 'The Academy of Medicine calls the attention of the public authorities to the necessity of modifying, in conformity with the laws of hygiene, and the necessities of the physical development of children and young people, the present arrangements of our scholastic establishments. It thinks that the colleges and lycées for boarders should be removed to the country; that wide, open spaces should be set apart for games; and that the class-rooms should be improved as regards lighting and ventilation.' Without dealing with the course of study, which it desires to see simplified, the Academy calls special attention to the following points: Increase of the time for sleep as regards young children; for all pupils, a diminution of the time devoted to study and classes — that is to say, to sedentary occupations — and a proportional increase of the time for amusement and exercise; the absolute necessity of submitting all the pupils to daily exercise in physical training, proportioned to their age; namely, walking, running, jumping, formations, evolutions, regulated and prescribed movements, gymnastics with apparatus, fencing of every kind, games of strength, etc."

CARMINATIVES, AND THE ABSORPTION OF GAS BY THE INTESTINES.

THE *Practitioner* reproduces from the St. Bartholomew's Hospital Reports, Vol. XXII, some experiments just published, which were performed several years ago by Drs. Lauder Brunton and Cash, with a view to determine how carminatives act in relieving flatulence. The gases used in the experiments were atmospheric air, carbonic acid gas, hydrogen, marsh gas, coal gas, and sulphuretted hydrogen. With the exception of one experiment the oil of cloves was the only carminative used. In each experiment they first tested the gases alone, and then again after the administration of the carminative. They found that little or no absorption took place when atmospheric air, hydrogen, coal gas, or marsh gas was used, and the addition of the carminative did not seem to increase the absorption. It was only in the case of carbonic acid that the carminative seemed to aid in absorption, and this was due probably more to the effect on the movements of the intestine than to direct absorption of gas. The oil of cloves caused a marked increase in the secretion of the intestine — a fact which perhaps explains the advisability of combining carminatives with purgatives. In regard to sulphuretted hydrogen it was found that its absorption proceeded so rapidly as to produce even fatal poisoning, but carminatives did not exert much influence in increasing the absorption.

A NEW AID IN THE DIAGNOSIS OF GASTRIC DISEASE.

IT is a point of capital importance in the diagnosis and treatment of diseases of the stomach, to determine the motor power of the organ, or, to be more accurate, the period that elapses between the entrance of food through the cardiac orifice and its exit through the pylorus. The chemical properties of salol have enabled Ewald (*Weiner med. Presse*, 1887, No. 28) to accomplish this desirable object. The decomposition of this substance, and consequent appearance of salicylic acid in the urine, does not begin until it has passed into the small intestine. Salol may be mingled with the contents of the stomach, and kept at the temperature of the body for hours, without decomposition. This fact was determined by Ewald in twenty-five experiments. On the other hand, it is rapidly decomposed in the alkaline secretions of the intestine. In healthy persons salicylic acid appears in the urine in from one-half to one hour after the administration of salol. If this limit is overstepped, the delay may be attributed to pathological changes in the stomach. In eight typical cases of dilatation of the stomach studied by Ewald, salicylic acid could not be found in the urine until from two to three hours after the ingestion of salol, and in two obscure cases the same observer was enabled to detect dilatation by means of this delayed reaction.

This interesting observation is applicable, not only as a means of diagnosis, but as a test of the effect of treatment; for, by means of it Ewald has been enabled to determine that both electricity and massage hasten the passage of the chyme into the intestine.—*Medical News.*

A NEW SEXUAL SEDATIVE, *SALIX NIGRA*.

J. HUTCHINSON, M.D., writes in the *British Medical Journal*, July 30th, of his experience with the *salix nigra* or pussy-willow, his attention having been called to the virtues of the drug by a report in the "Transactions of the Texas State Medical Association," from Dr. Paine, who prescribed it successfully in cases of ovarian hyperæsthesia, uterine neuralgia, etc., and also in spermatorrhœa and nocturnal pollution. His verdict upon the drug is that it is a powerful sexual sedative, similar in its action to bromide, but without its depressing qualities.

Dr. Hutchinson obtained a supply of the fluid extract, and has been employing it for some months. The most numerous class of cases in which he exhibited the drug were women of nervous temperament, in whom the nervous irritability reaches its height at the menstrual period, when, along with the general *malaise*, is added a very decided pain in one or other ovary. They also suffered from hemicrania, the pain being situated above the left eyebrow, and resembling the feeling as if a nail were being driven into the skull

(clavus). Many of them, too, complained of pain under the left breast, and extending round to the back. On one or two occasions, he has noticed patients complaining of the above symptoms, and in only a moderate degree, under favorable conditions — as for example, long-continued anxiety or alcoholism — go from bad to worse, till they become hystero-epileptics. In cases of this kind, it is supposed that the centre of inhibition has in some way got out of gear, and the severity of the symptoms depends upon the amount of disturbance in this nerve-centre.

In cases where the ovarian distress was the symptom for which advice was sought, as being, in the patient's eyes, the most prominent, he usually succeeded in eliciting other indications of an irritable nervous system, and placed them upon half-drachm doses of the fluid extract of *salix nigra*, three times a day. In quite seventy-five per cent. of the patients so treated, a great amount of relief was obtained after two or three days' treatment. Not only was the ovarian hyperæsthesia relieved, but the nervous palpitation of the heart was abated, and the patient felt in every way stronger.

He has also given the drug in two cases of nocturnal emissions with marked benefit. The pollution ceased entirely while the drug was being taken, and for several months thereafter. Virile power and passion were not much, if at all diminished, but the relief from the ailment gave great satisfaction.

Correspondence.

THE UNIVERSITY OF MICHIGAN NOT GUILTY.

MEDICAL DEPARTMENT, UNIVERSITY OF MICHIGAN,
ANN ARBOR, August 23, 1887.

MR. EDITOR,—In your issue of August 11, on page 143 is a communication signed "Reader," whose object is to bestow deserved censure on the vicious haste with which some medical schools allow their students to complete the professional course. In mentioning a definite example your correspondent says, "The first course of lectures in this instance was taken at Ann Arbor, and the whole course was less than one year. *The same college* let a man through a few years ago, out of pity, after having decided that he was incompetent, because he attempted (?) suicide." The italics are mine. To the first sentence quoted I make no objection, though the author might have added the statement that by no possibility could the graduation have been recommended by the Medical Faculty of the University of Michigan. The second sentence is so ambiguous that one would wish that the author were as perspicuous a writer as he is a well-intentioned "Reader." The "same college" referred to is *not* the College of Medicine and Surgery at Ann Arbor. I think that no body of men is more earnestly endeavoring to elevate the standard of medical education in this country than the Medical Faculty at Ann Arbor. Yours respectfully,

HENRY SEWALL, M.D.,
Professor of Physiology.

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 20, 1887.

Deaths reported 2,685: under five years of age 1,178; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 709, consumption 288, lung diseases 113, diarrhœal diseases 467, diphtheria and croup 79, typhoid fever 74, malarial fever 36, whooping-cough 18, scarlet fever 12, cerebro-spinal meningitis 12, measles five, erysipelas three, pueperal fever two, small-pox (New York) one. From malarial fever, New Orleans 12, New York nine, Brooklyn five, Philadelphia four, Baltimore three, Charleston two, Nashville one. From whooping-cough, New York five, Baltimore four, Boston three, Brooklyn two, Philadelphia, Milwaukee, Nashville and Somerville one each. From scarlet fever, New York six, Philadelphia three, Brooklyn, Boston and Lawrence one each. From cerebro-spinal meningitis, New York six, Milwaukee two, Philadelphia, District of Columbia, Pittsburgh and Worcester one each. From measles, New York, Boston, Milwaukee, Fall River and New Bedford one each. From erysipelas, New York two, Baltimore one. From puerperal fever, New Orleans and District of Columbia one each.

In the 21 cities and greater towns of Massachusetts, with a population of 1,051,335 (population of the State 1,941,465) the total death-rate for the week was 27.05 against 27.83 and 30.01 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending August 20th, the death-rate was 22.9. Deaths reported 4,050: infants under one year of age 1,790; acute diseases of the respiratory organs (London) 158; diarrhœal diseases 973, whooping-cough 125, measles 93, scarlet fever 54, fever 30, diphtheria 17.

The death-rates ranged from 13.2 in Brighton to 39.3 in Preston; Birmingham 22.2; Bradford 22.5; Hull 20.7; Leeds 21.5; Leicester 27.3; Liverpool 26.8; London 21.8; Manchester 26.3; Newcastle-on-Tyne 29.6; Nottingham 23.5; Sheffield 26.7.

In Edinburgh 17.6; Glasgow 16.4; Dublin 29.6.

The meteorological record for the week ending August 20, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Aug. 20, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 20, 1887, TO AUGUST 26, 1887

BAILY, JOSEPH C., lieutenant colonel and assistant medical purveyor. Granted leave of absence for one month. Par. 10, S. O. 191, A. G. O., August 18, 1887.

TREMAINE, W. S., major and surgeon. Found incapacitated for active service, by an army retiring board, and extension of leave of absence on account of sickness still further extended until further orders. Par. 9, S. O. 192, A. G. O., August 19, 1887.

BARTHOLF, JOHN H., major and surgeon. Leave of absence extended one month. Par. 7, S. O. 195, A. G. O., August 24, 1887.

PATZKI, JULIUS H., captain and assistant surgeon. Granted leave of absence for one month. Par. 15, S. O. 195, A. G. O., August 23, 1887.

MATTHEWS, WASHINGTON, captain and assistant surgeon. Ordered to proceed to Phœnix, Arizona Ter., on public business, and on completion thereof to return to his proper station, S. G. O. Par. 21, S. O. 195, A. G. O., August 23, 1887.

TAYLOR, BLAIR D., captain and assistant surgeon. Granted leave of absence for twenty days, to take effect on or about August 31, 1887. Par. 7, S. O. 195, A. G. O., August 20, 1887.

SWIFT, E. L., first lieutenant and assistant surgeon. Ordered to report in person to Commanding General, Division of the Pacific, for duty with troops at Round Valley, Indian Reservation. Par. 20, S. O., 195, A. G. O., August 23, 1887.

JOHNSON, HENRY, captain and medical storekeeper. Ordered in addition to his present duties, to take charge of the office and perform the duties of acting assistant medical purveyor in New York City during the temporary absence on leave of Lieutenant Colonel Jos. C. Baily, assistant medical purveyor. Par. 11, S. O. 191, A. G. O., August 18, 1887.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING AUGUST 20, 1887.

LONG, W. H., surgeon. Leave extended six days on account of sickness, August 13, 1887.

FESSENDEN, C. S. D., surgeon. Leave extended thirty days on account of sickness, August 19, 1887.

GODFREY, JOHN, surgeon. Granted leave of absence for thirty days, August 17, 1887.

GLENNAN, A. H., passed assistant surgeon. Granted leave of absence for thirty days, August 18, 1887.

MCINTOSH, W. P., assistant surgeon. Granted leave of absence for twenty-five days on account of sickness, August 17, 1887.

BOOKS AND PAMPHLETS RECEIVED.

THE RELATION OF TEA-DRINKING TO DISORDERS OF THE NERVOUS SYSTEM.[1]

BY WILLIAM N. BULLARD, M.D., OF BOSTON.

The action of tea, as generally drunk, upon the system is two-fold: (1) mechanical, and (2) physiological. It acts mechanically upon the stomach through the bulk of fluid introduced, causing, when taken in large quantities, a certain distension, and it also, thus taken, acts to produce, aside from any chemical effect, a mechanical diuresis. As usually swallowed, also, that is, hot, and almost boiling, it acts as a direct irritant to the mucous membrane of the stomach, tending to bring on a condition of gastric catarrh (Lauder Brunton), and likewise, as a powerful stimulant to the heart, both directly through the diaphragm, and indirectly through stimulation of the gastric nerves.

The physiological action of tea is less well known. That it is, in large doses, a cerebral stimulant there is no question, but beyond this, the exact method of its action upon the nervous system, and how far each of its constituents plays a part therein, still remains undetermined. Much more is clear in regard to its action on the digestive organs, and, had I time, I should be glad to place before you the results of some of the extremely interesting experiments made by late investigators. As it is, I can only refer to them in the most hasty way, before passing on to the proper subject of this paper.

In the first place, Dr. Roberts has found that tea has a strongly inhibitory action upon the salivary digestion, even when in very minute proportion, completely paralyzing the action of the saliva. This he supposed to be due to the action of the tannin. This action may be partially avoided, either by drinking the tea after the meal in such a way that the salivary digestion has taken place before the ingestion of the tea, or by the addition of a little carbonate of soda, which seems to enable the saliva to act. The deterrent effect of tea upon the gastric digestion is well known. Aside from any irritating action upon the gastric mucous membrane, it uniformly retards both peptic and pancreatic digestion, and, in this way, exerts a very strong injurious influence over the whole system. According to the investigations of Dr. James W. Fraser, very lately published, it retards "the digestion and absorption of all the nitrogenized proximate principles of dietetic substances, when peptic and pancreatic digestion are taken together."

From these physiological data, it is easy to see what effect we should naturally expect from the abuse of tea. How these expectations are verified clinically, I have already, in part, endeavored to show in regard to one class of cases.

More than a year ago, in April, 1886, I published a short paper containing an account of some investigations on the subject of chronic tea-poisoning. At that time, I had examined one hundred and sixty-three cases of tea-drinkers, mostly women, and also for purposes of comparison, one hundred and forty-eight persons in whom symptoms existed more or less closely resembling those caused by tea-poisoning, but in whom I was not inclined to attribute the symptoms to the abuse of tea. The results which I arrived at from that investigation are as follows:

(1) That the action of tea is cumulative.

(2) That its action is more pronounced on the young, and on those subject to anæmia, or in a depressed physical condition, although persons otherwise healthy not infrequently show toxic symptoms.

(3) That among the class of people under consideration,[2] who, as a rule, use medium grades of Oolong and Souchong (English Breakfast Tea), the average amount needed to cause toxic symptoms is a little less than five cups *per diem*.

(4) That chronic tea-poisoning is a frequent affection, and that its most common symptoms are loss of appetite, dyspepsia, palpitation, headache, vomiting and nausea, combined with nervousness and various forms of functional nervous affections, hysterical or neuralgic. These symptoms are frequently accompanied by constipation, and pain in the left side or cardiac region.

These results have thus far only been confirmed by further observation and examination of this class of tea-drinkers.

But it is not on these, as a whole, that I desire to dwell. My especial object, to-day, is to present to you as clearly and definitely as possible the relation which exists between long-continued or chronic tea-drinking and various forms of nervous derangement. First, however, I desire to state distinctly that in what follows, reference is made only to *chronic* tea-drinkers. I do not intend to discuss to-day the symptoms produced by acute tea-poisoning, that is, those following the inbibition of a single large dose of tea, or of a few such doses, nor do we refer to professional tea-tasters. On the contrary, those cases we are considering belong to that large class, mostly composed of women, who, for weeks, months, or years, are accustomed to drink daily a considerable amount of tea, often without taking a proper supply of other nourishment, and frequently when they are, from other causes, in an exhausted or anæmic condition. And here we beg leave to emphasize a fact, which may, perchance, seem to some to be almost self-evident, but which yet has apparently not been clearly comprehended by some of the more recent writers on this subject, and this is that the effect of tea varies much in different persons, according to their physical condition and to other circumstances, and again, in the same person at different times. On those of sedentary habits or of weak constitution, tea has undoubtedly a stronger influence than on those who are constantly engaged in active exercise in the open air, and who are physically vigorous. Moreover, much depends on the amount of food taken with the tea, or at other times. Many women drink their tea, not only with their meals, but at other times also, thereby increasing its deleterious influence, while not a few, and these are the cases in which it specially shows its bad effects, use the tea as a stimulant to support themselves for their daily work, while they take little or no other food. The amount of tea taken in this way which will cause unpleasant symptoms is often much smaller than that which can be taken in a proper manner without any evil results. Again, as people become

[1] Read before the Massachusetts Medical Society, June 7, 1887, and recommended for publication by the Society.

[2] Those who applied for medical treatment at the Out-Patient Department of the Carney Hospital, or at the Women's Room in the Boston Dispensary.

weak or anæmic from overwork, from want of fresh air, or from any other cause, the amount of tea which they could previously take with impunity exerts its toxic action upon the enfeebled system, so that the same person may, at different times and under different circumstances, be variously affected by the same amount.

These things being premised, we will pass to the consideration of the special subject of this paper.

It is the great prominence of functional affections of the nervous system, which, in combination with the other symptoms, gives its peculiar character to the symptom-complex of tea-poisoning. It is precisely these (functional) affections of the nervous system, which, when they assume a prominent position in connection with the ordinary symptoms of dyspepsia, should lead us to consider the probability of the toxic action of tea. What these symptoms are, I will endeavor to state. So far as my personal observations go, they are always functional; but it is not impossible that a long-continued inbibition of very large doses of tea, after the premonitory symptoms had been neglected, might, in addition to other causes, eventually help to produce some organic lesion in those previously predisposed. But of this I have personally seen no evidence.

The first sign of disorder of the nervous system in chronic tea-drinkers is their general restlessness and nervousness. The normal condition of the nervous system is disturbed and replaced by a condition of hyper-excitability or of less stable equilibrium. This is shown by their want of calmness, their general restlessness and irritability, and the desire to be constantly moving, while at the same time there is a subjective sensation of loss of self-control and of inability to act slowly. Such persons are subject to exaggerated efforts from ordinary impressions; they are easily startled, jump at unexpected noises or sensations, or, in other words, react too freely to slight external influences. The moral balance is also affected. This general condition occurs in nearly all those who have been for any length of time under the toxic influence of tea. Indeed, so universal is it in persons of this class that I should hesitate to make a diagnosis of chronic tea poisoning in a case where it was absent, unless the other symptoms were so marked as to render the affection unmistakable. As the toxic effect of the tea increases, this symptom or series of symptoms is apt to increase in severity and may assume some definite form or develop in some special direction. Some patients, for example, labor under a constant fear that something terrible is about to happen, though without any idea as to the nature of the terrible event which is to occur; others, again, say that they become excited whenever they are in a crowd, feeling as though they were afraid of some one, although they knew all the while that this sensation is wholly causeless. From these conditions it is but a step to the various forms of mental weakness and to hysteria.

The next most frequent symptom of nervous origin is palpitation, which was noted in forty-nine per cent. of our cases, and which probably occurred in a still larger proportion. It is but fair, however, to state that this symptom is not complained of in some otherwise well-developed cases, and that at the time of examination no irregularity of the heart-beat in them could be detected.

These two symptoms, nervousness and palpitation, are, however, common to a large variety of affections, and may be produced in many different ways. In chronic tea poisoning they may be caused either directly by the direct action of the tea upon the nervous system, or indirectly through the production of gastric or intestinal dyspesia. Nervousness, moreover, is so common a concomitant of anæmia or physical depression from any cause that, considered by itself, it could not be judged as in any way distinctive, and it is only from its undue development in proportion to the other symptoms that it acquires value as a factor in the diagnosis. The last clause applies also to palpitation, which frequently occurs, though perhaps not to quite the same extent, in simple dyspepsia, where tea is out of the question. Inasmuch, then, as these two symptoms, nervousness and palpitation, are of such common occurrence in other affections, and, as in the case of the latter symptom, it is not certain that all cases are of nervous origin, we shall for the present make a distinction between them and the more definite symptoms of nervous disorder which accompany chronic tea poisoning, and consider the latter by themselves, only placing among them the more extreme cases of nervousness, such as those already mentioned, where some special form is assumed.

In considering, therefore, the proportion of cases in which symptoms of nervous disorders occur, we shall leave out of account those in which nothing more definite than nervousness or palpitation was noted. For while unquestionably many of these cases, probably by far the greater proportion, really belong under this heading, inasmuch as it is impossible with our present knowledge to determine how far this is the case, it seems advisable to consider in this class only those symptoms about which no doubt can be expressed. We shall likewise omit from our classification among cases which have special nervous symptoms all those in which bilateral headaches occurred, unless there appear some distinct reason for the belief that these headaches were either neuralgias proper or otherwise of true nervous origin.

CASES WITH SPECIAL NERVOUS SYMPTOMS.

The total number of cases of this class of which I have records, is fifty. The principal divisions are as follows:

Neuralgia	20	Hysteria	6
Hemicrania	11	Mental Asthenia	3
Migraine	8	(Tremor	5)[3]

By far the most common form of special nervous disorder found in chronic tea drinkers is neuralgia, and of this I have records of twenty cases. The neuralgia does not appear to have any special tendency to affect any particular nerve or group of nerves, but it apparently attacks the locus minimæ resistentiæ, being found in one person in one portion of the body, in another person in some other. The most frequent form was facial neuralgia, which occurred in six cases. Intercostal neuralgia was found in five, occipital neuralgia (including occipital headaches) in five, and sciatica in four. General neuralgia was found in two; brachial, abdominal, lingual and post-auricular in one each.

The average number of cups of tea drunk in each case was:

[3] See later.

Intercostal Neuralgia	5 cases.	4.4 cups per diem.
Occipital Neuralgia	5 cases.	5.5 " "
Facial Neuralgia	2 cases.	6.25 " "
Sciatica	2 cases.	5.25 " "
General Neuralgia	1 case.	8.00 " "
Brachial Neuralgia	1 case.	5.00 " "
Abdominal Neuralgia	1 case.	6.00 " "
Post-auricular Neuralgia	1 case.	6.00 " "
Total average		5.40 " "

That all these cases of neuralgia are directly due to tea we do not believe; indeed, in some of the cases there is proof of other causes; but in all of them there is reason to suppose that the tea has played some part. In a large proportion of these cases there was either neuralgia in more than one part of the body, or else some other symptom directly referable to the nervous system.

I will here relate one of the more typical cases.

Case I. A woman, twenty-three years of age, came to the Out-Patient Department of the Carney Hospital on the 30th of March, 1885. She was suffering at that time from abdominal neuralgia, a dull pain in the sciatic region, and pain over the left breast. Palpitation. Constipation. Appetite good. Is nursing a child fifteen months old. She drinks tea, five cups or more a day, taking it at every meal, and between meals also. No coffee.

Physical examination shows some tenderness over the left half of the abdomen. Nothing abnormal detected about the heart or elsewhere. Diagnosis: hyperlactation. Tea. Abdominal neuralgia. Treatment: iron. Liquorice powder. To stop tea. To wean the baby.

This patient was seen again in March, 1887, two years later. She stated that she was decidedly better for a considerable time after her visit to the hospital. She had stopped the tea as directed, though she still took one cup occasionally. She had some pain in the left side ever since she was at the hospital, though this had been better for some time after. One year ago she had another child.

She is subject to pains all over at times, but especially in the arms and on the right side of the body. She has now a right facial neuralgia of a week's standing, due to a carious tooth. She has no headaches and but slight dyspeptic trouble. Palpitation, however, is severe. She is very nervous and easily frightened.

How much of the neuralgia present in this case was due to the influence of tea, and how much was due to other causes, anæmia from excessive nursing and a naturally neurotic disposition, it is impossible to say. It is only by collecting a large number of cases like the foregoing and by collation and comparison thereof that we can arrive at any reliable conclusion. The persistence of the nervousness, palpitation and neuralgia so long after the giving up of the tea proves, of course, that the tea is no longer in any part an active cause of their presence. But, on the other hand, there can be but little question that it has in combination with other factors aided in bringing the system into a condition of diminished or depressed nervous vitality, from which it has not been able to recover while under unfavorable surroundings.

Next to neuralgia the most frequent form of special nervous disturbance met with in cases of chronic tea poisoning is migraine and hemicrania. We shall consider these separately, classing under migraine all bilateral headaches, accompanied by nausea or vomiting, not apparently connected with gastric difficulties, and recurring with more or less frequency.

Migraine.— We have under this head five reliable cases. It is on account of the great difficulty of determining the precise source of these headaches that I separated them from the group of hemicrania; yet the same rules apply in a general way to both.

Case II. Woman, sixty. First seen May 18, 1885. Complains of dull frontal headache, which is followed by general weakness of all the muscles, so that she can scarcely move about. The headache is accompanied by nausea, but there is no vomiting. She is subject to attacks of vertigo and is afraid of falling. Appetite poor. Bowels irregular. Drinks *strong* tea — "pure black" — three times a day, and occasionally between meals. Mother has attacks of sleep, which last so long, that she has to be wakened.

May 26, 1885. Improved.

Patient was next seen in June, 1887. States that the headaches ceased entirely, but have lately recommenced again under the form of a right hemicrania. There is no nausea or vomiting with the headaches, but she is weak and has to lie down when they come. Dizziness slight, much less than formerly. Appetite fair. Bowels regular. Stopped the tea as directed in 1885, and, otherwise than the headaches, which have lately reappeared has been perfectly well since. Drinks no coffee. Never had neuralgia or rheumatism.

(This case which has been placed under migraine, should, perhaps, in view of the later history, rather come under the head of hemicrania. It illustrates the closeness of the relation between the two.)

Hemicrania.— Of this we have eleven cases accompanying tea poisoning, not including one case in which the patient drank both tea and coffee. The connection between hemicrania and tea is certainly a very close one. Alcott, as far back as 1839, called attention to tea as a cause of migraine. Whether it be so or not, which I consider doubtful, there can be no question but that there is a close relation between this affection and tea drinking. Since my attention has been drawn to the subject I cannot recollect having seen a single case of hemicrania in which the patient did not drink tea in greater or less quantity.

Hemicrania existed in eleven per cent. of our tea-patients. In some of these, it could not have been entirely due to the tea, inasmuch as it had been inherited, or had existed before the tea-drinking began. In spite of Alcott's statement, and those of other writers in this direction, I cannot help feeling that the influence of tea as a *causative* factor in hemicrania has been exaggerated. That it may, and, in certain cases, does tend to increase the frequency and severity of the attacks, is possible. But the evidence tends much more in a different direction. It points to the fact that hemicrania, or the condition of the system which exists in hemicrania, is one which specially craves the momentary stimulus imparted by tea, and causes a demand for it which is easily gratified. There is in my mind but little doubt that the relationship between tea and hemicrania is due rather to the demand of the nervous system in these patients for a mild stimulant, rendering them more inclined than the average to drink tea, than to any causative effect which the tea may exert. The average amount of tea-drinking in our cases of hemicrania was 4.5 cups (seven cases), or, omitting one case in which the patient was very much debilitated, having apex catarrh, and nursing, at the same time, a baby seven months old, and where the

amount drunk was only two cups *per diem* — an exceptionally small amount to have any serious effect — the average was 4.9 cups.

Paræsthesia. The only other form of sensory neurosis which has been present in any of our cases is paræsthesia. This occurred in two cases, in one of which numbness of the hands and feet was complained of; in the other, burning of the palms and soles, and a sensation as of cold water pouring over the head and forehead. In the latter case, the symptoms were promptly cured by phosphoric acid and the omission of tea. In the former case, the symptoms mentioned, in company with neuralgia, palpitation, and general nervousness, continued for two years, the patient not having given up the use of tea, and not having been under medical treatment. These two cases are not of sufficient importance to lead us to suppose, in the absence of other evidence, that the tea had any direct connection with the paræsthesia. The amount drunk was not excessive in either case, in one only four, and in the other 4.5 cups *per diem.*

MOTOR NEUROSES.

There is no evidence in any case that I have thus far seen that tea, as drunk in the cases we have under consideration, has any marked effect in producing motor neuroses. There is, on the other hand no question but that, when such neuroses exist, if they be not organic, tea should be carefully avoided, as tending to further and promote their development. This is especially the case in chorea and all allied affections.

We find among our cases one in which the patient, a boy sixteen years old, began to have choreic movements two years after he had given up the tea (green tea), which he had previously drunk in excess. This was unquestionably a mere coincidence. Among all the cases of chorea which have come under my personal observation within the last three years, and of which very full and careful records have been kept — seventy-five — not one has been found in which tea-drinking could be assigned as the cause.

Tremor occurred in five cases. Two of these were probably cases of organic disease, two had mental symptoms and others of a character unusual in chronic tea-poisoning, leaving only one in which there seemed a fair probability that the tremor might have been due to the tea. There is no question but that tremor due to tea occurs in tea-tasters, and is frequent in cases of acute tea-poisoning, and Slayter, of Halifax, relates a very interesting case of delirium tremens caused by chewing tea, but in the class of cases of which I treat here, I have thus far failed to find any evidence of its occurrence.

Muscular cramps, or tonic contraction of muscles, occurred in three cases. In none of these was the history sufficiently definite to enable us to refer them to the tea.

HYSTERIA AND NEURASTHENIA.

Neurasthenia. This term serves to cover a number of cases having more or less indefinite symptoms, and standing, as it were, midway between simple nervousness and marked hysteria. The word, as Dr. Wood states, "denotes not a distinct disease, but a condition of the body." It is commonly used to comprise those indefinite forms of functional nervous exhaustion which cannot, as yet, be placed in any other category. As our knowledge of functional nervous conditions advances, and we are enabled to classify them more accurately, more and more cases will be removed from the domain of neurasthenia, and placed under some more exact and appropriate title. As things are now, it is impossible to draw any accurate line between those cases which should naturally be classed here, and those which should more properly fall under other headings. Many cases of exaggerated nervousness are named neurasthenic, and many cases of slight or even moderately advanced hysteria come under this head. For this reason, we shall not consider any cases here, but shall try to define and classify more accurately all those cases which were thus designated in the records or elsewhere.

(Of the four cases which were placed originally under this title, two fairly belong under the head of hysteria, and two to the class of exaggerated nervousness to which I have already referred. The latter cases point to a certain mental asthenia, and, if more strongly developed, might justly be placed among the milder forms of monomaniacal weakness.)

Hysteria. Under this heading I have placed six cases, including all those of functional paralysis.

I. Woman, sixty. Drinks three to four bowls of tea *per diem*, though she has lately diminished the quantity to two or three bowls. Is emotional; cries very easily. Globus hystericus. Temporary paresis of right arm, accompanied by pain.

II. Woman, fifty. Drinks strong tea, six cups or more *per diem*. Has functional paralysis of the vocal cords.

III. Woman, thirty-four. Came to Carney Hospital, May 6, 1885. Had then been emotional and hysterical for two years. Complained, at that time, of nervousness, general weakness, palpitation, and loss of appetite, and was subject to bilateral frontal headaches. Drank tea at each meal, and between meals. Treatment: to leave off drinking tea. Dilute phosphoric acid.

Was next seen two years later, in May, 1887. States that she got well after her visit to the hospital, and has been well since. Slept better, and was not so nervous after leaving off the tea, which she did completely for a time. Now takes two cups of tea *per diem* with meals, sometimes replacing one with a cup of coffee. Except that she is slightly nervous and has a little dyspepsia, is perfectly well. Never had either rheumatism or neuralgia.

IV. Woman, forty-five. Always nervous, but lately worse, and irritable with the children and other people. Feels as though she wanted to cry. Subject to hemicrania on the left side. Pain just below the right scapula, and also in the left side. Occasional palpitation. Appetite fair. Constipation. Occasional severe pain over the epigastrium; otherwise, no dyspeptic symptoms. Youngest child three years old. No uterine symptoms. Drinks about five cups of tea a day; coffee rarely. Is pale, thin, and weak. Tongue and lips pale. Heart normal in size; systolic souffle over pulmonary artery. Nothing else abnormal detected anywhere.

The other two cases are of the same general character as the preceding. In one of them, among the prominent symptoms were lingual neuralgia and functional aphonia.

These cases are of considerable interest as pointing to the influence of tea on hysterical women. That it exerts a specially deleterious effect on the majority of this class there can be but little doubt. That a few

large doses of strong tea act to stimulate the nerves is well known, but the depressing effect of regularly repeated small doses continued over a considerable length of time has been less frequently emphasized.

Certainly the number of those suffering from hysteria among our tea-patients was an uncommonly large one, six out of about 170, this is one out of 28, and this from a general clinic and not from one specially devoted to nervous disease.

In cases of this class I believe it to be of the first importance that either all tea should be strictly prohibited, or that it should be given only on the order of the physician and with great circumspection. I regard it as extremely probable, though not yet absolutely proved, that in all cases where the nervous system is deranged, as in hysteria, and the allied affections, the action of tea is more powerful than on the normal subject and its influence for good or evil increased.

Mental Asthenia.— In those cases of nervous instability in which the mental symptoms are especially prominent, we are naturally led to be more than ordinarily cautious. The general principles which apply in cases of hysteria hold good also here. Happily most of these cases, though extremely trying both to the family and to the physician, will, under proper care and treatment, attain an ultimate cure. Chronic by nature, many of these cases test the skill and patience even of the specialist.

Having now given some of the data gathered from our observations on chronic tea-poisoning in regard to the frequency with which it is accompanied by the various forms of neurosis, it behooves us to state as clearly as possible our opinion in regard to the relation existing between the two. The conclusions which we have reached are as follows:

(1) Chronic tea-poisoning produces a condition of irritability or hyperexcitability of the nervous system, and does this both directly by the action of the tea upon the nervous system and indirectly by the production of gastric derangement.

(2) Tea taken frequently and in moderate doses for a considerable period of time tends therefore to place the nervous system in a condition in which it is more easily affected injuriously by slight external influences. It therefore favors the production of many forms of functional neuroses, and, if such neuroses already exist, aids in their continuance.

(3) There is no evidence that tea taken in the manner described causes any organic nervous lesion, but it is probable that if such nervous lesion should exist, tea thus taken might tend to cause an aggravation and continuance of certain symptoms.

(4) There is no evidence that chronic tea-poisoning produces unaided any serious functional neurosis in persons not in any way specially predisposed thereto. It does, however, in the manner above described act as an important factor in the production of neuralgia, hysteria and allied affections.

(5) When taken constantly in very large doses dyspeptic symptoms usually intervene before irreparable harm is done to the nervous system.

(6) In hemicrania and possibly some other functional neuroses there is probably a craving on the part of the nervous system for a slight stimulation, which is better afforded by tea than by any other equally accessible article, and for this reason patients with hemicrania are so frequently tea-drinkers.

In conclusion, I beg to say that I should be glad to receive information from members of this Society in regard to the frequency with which tea is used among their patients and in the various places where they practice, and of the results which have come under their observation.

A CONTRIBUTION TO THE STUDY OF THE ETIOLOGY OF THE SUMMER DIARRHŒA OF INFANTS.[1]

BY HENRY C. HAVEN, M.D., OF BOSTON.

In a communication entitled "The Etiology and Treatment of the Summer Diarrhœa of Infants," presented to this Society at its last annual meeting, I expressed myself somewhat as follows: —

"According to the United States Census of 1880 Massachusetts has a percentage of total deaths under one year to aggregate deaths of 21.99; the lowest State but one, Pennsylvania.

"Massachusetts has a percentage of total deaths from diarrhœal diseases to aggregate deaths of 7.83, only four of the thirty States ranking lower: yet in this same State in 1884 there were 2,089 deaths from cholera infantum, and in the twenty-two years from 1863 to 1884 40,006 infants died from the same cause.

"These figures only partially show the total mortality from diarrhœal diseases under one year; for according to the State Registration Report the number of deaths in Boston from cholera infantum in 1884 was 504, while by the fuller report of the Boston Board of Health the number of infants dying from *diarrhœal diseases* was 710, a difference of 206. . . .

"Urbane Residence. A second condition which meets with general acceptance as a necessary factor is Density of Population, which, as a rule, is only found in cities and large towns.

"This view is, so far as I know, at present held by all the writers on the subject, whether English, Continental or American.

"The following are fair representative quotations: —

"Dr. Eustace Smith, in his 'Practical Treatise on the Diseases of Children,' makes the following statement as to the causation of 'choleraic diarrhœa': 'It is especially a complaint of warm weather, and summer heat must be looked upon as a powerful predisposing cause of the disease. Other agencies, however, must come in as exciting causes, for the affection is not common in country places, and indeed is *rarely seen out of cities*.'

"Meigs and Pepper in their book 'Diseases of Children' say of 'Entero-Colitis,' 'The most active causes of the disease are the heats of summer, *residence in large cities*, — and this includes higher heat than residence in rural districts, — with greater density of population and more copious filth emanations and improper alimentation.'

"Dr. J. Lewis Smith, in 'Diseases of Infancy and Childhood,' says 'that "cholera infantum," or as it is sometimes called "choleriform diarrhœa," is a disease of the summer months, *and with exceptional cases, of the cities*.'

"Dr. Lewis Starr states in regard to its etiology that, 'like entero-colitis, it is a *disease of cities*,[2] find-

[1] Read before the Massachusetts Medical Society, June 8, 1887, and recommended for publication by the Society.

[2] Italics mine.

ing its victims chiefly among those that live in poverty and squalor.'"

"It seems as if there could be no question as to these views being correct, and yet in studying the occurrence of the disease in Massachusetts from the mortality reports during the five years from 1880 to 1884, certain apparent facts present themselves which it is difficult to reconcile with the ordinarily accepted opinions.

"A few preliminary words are necessary as to the character and value of these statistics. They are taken from the State Registration reports which are deficient in many respects.

"I have only been able to group the deaths from cholera infantum instead of, as I wished, the deaths under one year from all the diarrhœal diseases; the later being nowhere accessible. I have assumed, however, that a death registered from cholera infantum must at least be a death caused by diarrhœal disease in an infant. To just the extent that this assumption is not correct the conclusions are invalidated, but it seems to me it must only be in exceptional cases that a death from cholera infantum does *not* mean a death from diarrhœal disease; and such exception again may as well occur in the city as in the country.

"That cholera infantum in Massachusetts is practically the same disease that we have under consideration is shown by the chart, which gives the curve by months of the mean State mortality for five years (*vide* Chart I). The curve in the city and country is presumably the same, although the registration reports do not give the data for constructing graphic curves which will verify this statement.

"To return, however, to the statistics of the mortality from cholera infantum in Massachusetts. On studying the number of cases occurring in every town in the State during the five years from 1880 to 1884 I find such apparently contradictory facts that, without a more definite knowledge of the *exact* cause of death and of the differing conditions prevailing in the different towns, it does not seem safe to draw any deductions from the statistics.

"I will only call attention to one table (Table A) which seems of some value.

"In this the deaths from cholera infantum are compared with the population, with the births, and with the total deaths under one year in the three following groups:

"(1) Seventeen cities with a population of over 15,000; a total population of 892,077.

"(2) The towns of 15,000 to 5,000; a total population of 331,644.

"(3) The towns under 5,000 (country districts); a total population of 559,364.

"In this table several rather startling figures meet the eye. In the per cent. of cholera infantum deaths to total deaths *under one year* the city and country are *identical*, 27.4. In the per cent. of cholera infantum deaths to births the country shows the best, but even here not as well as the towns of 5,000 to 15,000 population. In the per cent. of all deaths under one to births the cities show the worst, but the towns of 5,000 to 15,000 and the country districts show a very slight difference, and that *against* the country.

"*That is*, these figures, as far as they go, show that while the prevalent opinion is correct that the city is (for some reason) less healthy than the country for babies — inasmuch as 18.1 of those born die under one year in the city against 13.4 in the country, and as, moreover, 5.4 infants under one year die in 1,000 of the population, against 2.4 in the country, more than twice as many — they do *not* verify the ordinarily accepted opinion as to the relative frequency of cholera infantum in the two districts compared as a cause of death in infancy.

"How far these apparent facts will be corroborated by the further study I hope to make is uncertain."

The object of this paper is to present the results of a further study made during the past year.

As neither the deaths under one year from cholera infantum or diarrhœal diseases are stated in the State Registrar's report I have had a rescript made from the original returns of the Age (in months and days), Sex, Color, Birthplace, Residence, and Nationality of every infant dying under one year of age in Massachusetts in the five years 1880 to 1884, together with the date and cause of death.

The deaths from diarrhœal diseases include all these registered as dying from any of the following causes: — Cholera Infantum, Cholera Morbus, Diarrhœa, Dysentery, Enteritis, Entero-Colitis, Gastritis, Gastro-Enteritis, Gastro-Intestinal Catarrh, Inflammation of the Bowels, and Inflammation of the Stomach.

It was said in the former paper: "The curve [the curve, that is, of the mean monthly mortality from Cholera Infantum] is presumably the same in the city and country, although the registration reports do not give the necessary data for their separate construction."

Actual statistics show the following average mean monthly mortality in Massachusetts during the years 1880–1884, from deaths under one year from diarrhœal diseases (in the State as a whole, and in the city and country districts, respectively; *vide* Charts II and III).

It will be seen that the original assumption is entirely borne out, the curves being identical in the two districts.

The second study that has been made from the actual statistics is in reference to the extent of the effect of urban residence.

Is it, as is generally supposed, a most important factor in the production of infantile diarrhœal disease, or can the suggestion of the statistics compiled from the registration report [Table A] be proved a fact by a more exact statistical examination?

To determine this, the total deaths under one year from diarrhœal diseases have been substituted, in Table A, for the deaths from cholera infantum, and the percentages figured on this basis. (*Vide* Table B.)

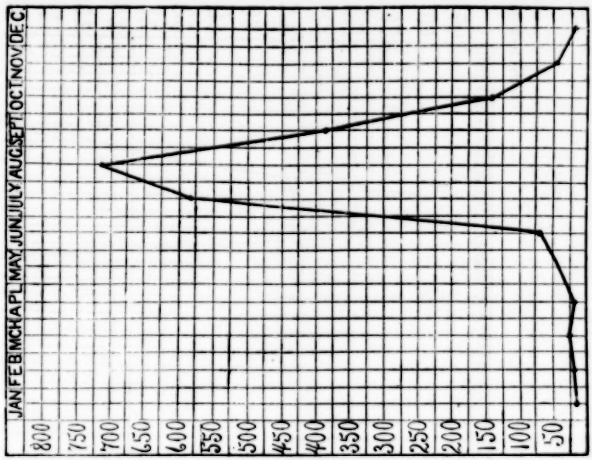
In order, moreover, to make the comparative test between city and country districts even more severe than in the former study, from the registrar's report I have included in the "country district" no towns having more than 3,000 population. In the former study, all towns under 5,000 were included in the country district.

The correctness of the statistics from which Table B is constructed cannot, it seems to me, be questioned. If not, it proves conclusively that in Massachusetts, at least, the factor of urban residence has not, during the last five years, entered into the etiological sum of the summer diarrhœa of infants to any *considerable* extent.

To be sure, in the comparison of deaths from either cholera infantum or diarrhœal diseases to population, the city compares most unfavorably with the country; but this is a most fallacious comparison, as has been explained above, and should be studied only in connec-

CHART II.

Average Deaths, under One Year of Age, from Diarrhœal Diseases, in Massachusetts, for Five Years, 1880–84.



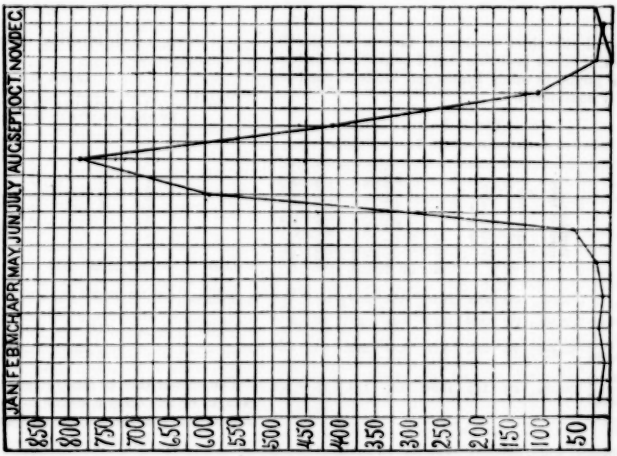


CHART I.

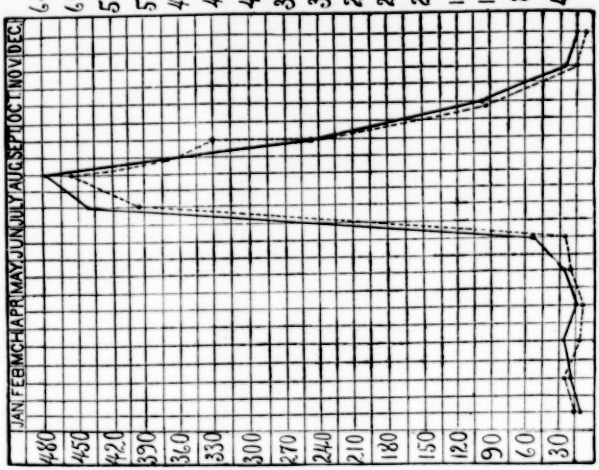
Average Deaths from Cholera Infantum in Massachusetts, for Five Years, 1880–84. *From Registration Report.*

tion with the relative birth-rates to the population in the two districts.

In the deaths from diarrhœal diseases to all deaths under one year, it will be seen that the difference in the city and country is comparatively small, being 28.9 in the former, against 24.9 in the latter.

There is only one condition that I can think of that can vitiate the conclusions from these statistics; that is, that first, many infants who have left the city for the summer die in the country from diarrhœal diseases, and that many more of this class would have died if they had remained in town; second, that many who are *attacked* in the city die in the country districts to which they are removed for treatment, and their deaths are registered as occurring in the "country districts."

But the total average yearly number of infants dying from diarrhœal disease in towns in which they were not born is not large, and, as such registers probably cover most of the cases instanced above, it does not seem as if the conclusions from Table B can be thereby vitiated.



The time has been too short to calculate the percentages after the substraction of these "non-resident deaths," but they will be published later with other tables.

If, then, city residence is *not*, to-day, in Massachu-

CHART III.

Average Deaths in Seventeen Cities of Massachusetts and in "Country Districts," from Diarrhœal Diseases, under One Year of Age. For Five Years, 1880–84.

—— Seventeen Cities. - - - - - Country Districts.

setts one of the chief etiological factors of infantile diarrhœa, it is not probable that it constitutes such an essential factor in other States and lands as has been generally considered.

TABLE A.

ANNUAL AVERAGE FOR FIVE YEARS, 1880–84.

	Population (census of 1885).	Deaths from cholera infantum.	Deaths under one year.	Births.	% of deaths from chol. infantum to 1000 of population.	% of chol. inf. to deaths under 1 yr.	% of cholera infantum to births.	All deaths under one yr. to births.
17 Cities	892,077	1320	4816	26,479	0.14	27.4	5.3	18.1
Rest of State	891,088	712	2639	19,723	0.08	26.9	3.6	13.9
Towns of 15,000 to 5,000	331,644	307	1167	8,757	0.09	26.3	3.5	13.3
Towns under 5,000 (country districts)	559,364	404	1472	10,965	0.07	27.4	3.6	13.4

Etiological knowledge is essential to rational therapeutics. My only object is to present facts bearing on the etiology of a disease which is the *third most fatal cause of death at all ages*, although limited in its time of action to the first year of life — a disease which is acknowledgely preventible, but which, nevertheless, is the only one of the miasmatic diseases (except diphtheria) which has, in Massachusetts, practically increased in the last five, as compared with the last forty-three years.

The summer diarrhœa of infancy is a zymotic disease, and I believe the only factor in its production to be fermentative changes in the food employed, or in the intestinal tract, resulting in a sepsis of the gastro-intestinal canal, and that all other conditions act only by and through their favoring or causing the presence of these changes.

TABLE B.

COMPARATIVE MEAN AVERAGES FOR FIVE YEARS, 1880-84, OF THE MORTALITY UNDER ONE YEAR OF AGE FROM DIARRHŒAL DISEASES IN MASSACHUSETTS.

	Population, 1880.	Births.	Birth rate per 1,000.	Deaths under one year.	Deaths from diarrhœal disease under one year.	% of deaths from diar. dis. to deaths under one year.	% of deaths from diar. dis. to births.	Of all deaths under 1 yr. to births.
17 Cities	892,077	26,232	29.3	4959	1435	28.9	5.47	18.1
Towns, 15,000 to 5,000	572,185	13,828	23.5	1724	464	26.9	3.35	12.4
Towns under 3,000	318,883	5,142	15.9	771	158	24.9	3.07	14.9

The sooner this is recognized, the sooner will the ravages of this disease cease to be the reproach that they now are to the science of preventive medicine.

— We learn that the use of gaseous enemata has been entirely abandoned in the fourth division, Bellevue Hospital, New York, where they have undergone the first and the longest trial.

— The *Medical and Surgical Reporter* says that three young internes of Newark City Hospital have received a very severe lesson. A patient was brought to the hospital, comatose. He was thought to be suffering from alcoholism, and he was treated accordingly, being given a douche and strong cutaneous irritation. The patient died, and on autopsy there was found a tumor of the brain. A coroner's jury investigated the case, and the internes were thereupon arrested for manslaughter.— A "severe lesson" indeed!

A SERIES OF INTRA-ABDOMINAL OPERATIONS.[1]

BY MAURICE H. RICHARDSON, M.D.,
Surgeon of the Massachusetts General, and Carney Hospitals.

THE following cases comprise all that have occurred in my experience since July, 1884. In giving these statistics I do not exclude any operation whatever in which the abdominal cavity has been opened except strangulated hernia and resection of bowel following internal strangulation.

Method of Operation. The incision has been made in the median line whenever practicable. In two of the cases it has been made elsewhere, once in the linea semilunaris and once parallel to the lower margin of the ribs. In all the cases the union was by first intention, and the only trouble was once in the diagonal incision, in which there was suppuration in the stitch holes. The suture of the wound was made in every case with silk and interruptedly, the stitches being about an inch apart. Care was taken in applying these stitches to have the peritoneum well included, and that the fascia transversalis should be also taken up. From these results it seems that it is unnecessary to make separate lines of suture for the peritoneum and other layers of the abdominal wall, which add, in my opinion, unnecessary time to the operation, and do not add to the chances of recovery.

Antiseptics. The carbolic spray was used with the first two operations and then abandoned. The greatest care was used in the disinfection of the hands after they had been most thoroughly cleansed with soap and the nail brush. No hand was allowed in the abdominal cavity except when it was necessary for the purposes of the operation. There was no unnecessary handling of the abdominal contents. No instrument was used that had not been thoroughly cleansed and disinfected previous to the operation and that had not been immersed in an antiseptic solution immediately before using, by the operator himself, who selected his instruments himself.

In some of the cases sponges were used which had been immersed in a five per cent. solution of carbolic acid for several weeks before the operation. In others, balls of worsted enclosed in cheese-cloth, of suitable size, which had been previously boiled, after the method of Dr. J. W. Elliot, were used.

In some of the later operations, in addition to the regular assistants, one was appointed to have general supervision of the antiseptics of the operation, who was well imbued with the principles and experienced in the practice of antiseptics, whose duty was to see that nothing approached the wound that was not perfectly aseptic. This plan worked admirably, and often prevented mistakes which would otherwise have been made in the excitement of the moment.

Another important element in these cases, in my opinion, was the effort on the part of the operator and the assistants to avoid unnecessary delay in the different steps of the operation. I may say that no time was taken at any of the following operations which was not essential for the removal of the tumor, checking hæmorrhage, cleansing the abdomen, and sewing up the wound. The time taken was therefore quite short in all the cases, and did not average more than twenty minutes in all. In one of the longest operations, the length of exposure of the intestines did not exceed forty-five minutes, and in most of them less than ten. In all of the cases where the peritoneum was opened the body was tightly swathed with dressings which were not disturbed, except for cause, till the end of a week.

[1] Read before the Boston Society for Medical Observation, April 19, 1887.

INTRA-PERITONEAL OPERATIONS. OVARIOTOMIES.

CASE I. July 25th, 1884. Carney Hospital. Single, age thirty-three. This woman had noticed a swelling of the abdomen for fifteen months which had gradually increased in size, had been accompanied by more or less discomfort, and was having a marked effect upon her general health. The tumor was found to be a unilocular cyst of the right broad ligament, which was sessile in the pelvis. It was removed with great difficulty, and there was very free hæmorrhage which was very hard to check. The operation lasted about an hour, owing to the fact that the bleeding vessels were so far down in the pelvis that it was extremely difficult to get at them. She never rallied from the shock of the operation, but gradually failed and died three days later.

CASE II. January 18th, 1885. Carney Hospital. This was a feeble woman of sixty-six years. The tumor which was very large had grown to its present size in eight months. Vomiting was very constant and she was much emaciated and very anæmic. There seemed at the outset very little hope of her surviving, but this appeared to us the only chance. The peritoneal cavity was found filled with a gelatinous fluid which was scooped out, and the tumor brought into view. The cyst was filled with the same jelly-like mass, and had to be removed in the same way. About thirty pounds were removed in this way. The peritoneal cavity was cleansed as well as possible and closed in the usual manner after the pedicle had been ligated and burned off with the cautery. She never rallied afterwards, and died January 25th. The tumor was examined by Dr. Whitney and found to be malignant.

CASE III. Carney Hospital. Married woman, age thirty-one. First appearance of symptoms about one year before admission. She had been tapped five times and enormous quantities of fluid withdrawn. May 14th, 1885, a multilocular cyst was removed without difficulty. The fluid weighed fifty-two pounds. In this as in all my ovariotomies the pedicle was ligated and burned, and then dropped back into the abdomen. About six months later the patient died with a return of the disease, without consulting any surgeon.

CASE IV. Carney Hospital. Married woman, age sixty. Had had thirteen children and two miscarriages. August 1st, 1885, a multilocular cyst weighing fifteen pounds was removed. Discharged well, August 26th.

CASE V. Married, age forty. July 13th, 1886, a unilocular cyst weighing thirty pounds. There were very numerous and extensive adhesions to the omentum and traverse colon which were divided with the cautery after tying interruptedly with catgut. Discharged well three weeks later. The convalescence was complicated by a severe phlebitis.

CASE VI. Massachusetts General Hospital. A young unmarried woman had been suffering for several years with acute pain in the region of the right ovary. At the same time she had been gradually increasing in

size. The thing, however, which compelled her to seek advice was the ever-present pain. At the operation, October 8th, 1886, the tumor, which was a unilocular cyst of the right ovary, was found to be very extensively adherent by recent peritonitis. It was removed without difficulty, and she made a rapid recovery.

CASE VII. St. Margaret's Home. A young woman, age twenty-one, gave a history of abdominal enlargement of four years standing. The tumor presented one interesting point in diagnosis. Over the pubes there was a small hard mass apparently adherent to the tumor, and which seemed to be a portion of it. It was finally thought to be the uterus riding upon and in front of the tumor. On this account some difficulty was anticipated. In the operation, November 18th, 1886, the abdomen was opened, and a unilocular non-adherent tumor was found and removed with the greatest ease. The hard mass was found to be the uterus, and its presence in that unusual position gave no difficulty whatever. The patient was discharged well in three weeks.

CASE VIII. At St. Margaret's. An anæmic woman of thirty-five had been suffering for two years with abdominal trouble. She had postponed the operation in the hope held out to her, by her "physician," that he could scatter the tumor by his medicine. Meanwhile, she had become much emaciated, and had suffered great and continuous pain and discomfort. February 12, 1887, I removed a multilocular cyst of the left ovary. There were extensive adhesions, which were divided with the cautery, and the pedicle was tied and dropped in the usual manner. She was discharged, well, in four weeks.

CASE IX. St. Margaret's. This was a young married woman, age thirty-three, who had first noticed that there was something wrong in June, 1886. Since then, the abdomen had enlarged steadily and rapidly. It was evident, on examination, that there was a large tumor of the abdomen, which was partly solid, and extended up under the liver. The tumor was removed March 15th, through a long incision, which extended above the umbilicus. She is, to-day, perfectly well, and about to return home.

OPERATIONS UPON THE STOMACH.

CASE X. Massachusetts General Hospital. Gastrotomy. This operation was done August 5, 1886, at the Massachusetts General Hospital, for the removal of a plate of teeth from the cardiac extremity of the œsophagus.[2] This patient has become as well and strong as ever, and has been able to do hard work. He has to be careful, however, to avoid exposure, because of the injury to the lungs, which have left him more or less susceptible to the effects of wet and cold.

CASE XI. Massachusetts General Hospital. Laparotomy for examination of tumor of the stomach. A woman of forty-four had suffered for eight months with vomiting (bloody at times), epigastric pains, emaciation, etc., with epigastric tumor. The diagnosis was considered quite doubtful, and was between cancer of the stomach and tumor of the spleen, in the opinion of those surgeons of the Massachusetts General Hospital who examined her. December 5, 1886, an incision was made in the median line, from the ensiform cartilage towards the umbilicus. The greater curvature of the stomach was exposed, and examined with the finger, and by the aid of the electric light. The anterior wall of the stomach was found to be the seat of a very extensive malignant disease, which had already infiltrated the surrounding parts. The wound was closed with silk, interrupted sutures, and she made a rapid recovery from the operation. After leaving the hospital, she regained her strength sufficiently to be up and out-of-doors. She has since died, and an autopsy showed the presence of cancer.

CASE XII. Massachusetts General Hospital. Penetrating wound of the abdominal cavity; enlargement of the cut, and exploration of the abdominal contents. Woman, age twenty-three. Shortly before entrance she had been stabbed with a sharp knife, and had received a deep cut through the abdominal wall, a little above and to the left of the umbilicus, with numerous cuts in other parts of the body, which were of little or no consequence. A small portion of omentum protruded from the wound. Under the most careful antiseptic precautions, the finger was introduced into the wound, which was found to communicate with the peritoneal cavity. The wound was then enlarged sufficiently (five inches) to allow a prolonged and careful examination of the intestines. No wound of the bowel having been found, the cut was sewed up, and patient put to bed. She was discharged, well, September 11, 1886. In this case, the question of interference was discussed, and the unanimous opinion of those present was that an examination should be made of the contents of the abdominal cavity, in order that the patient might avoid the chance of dying by a preventible cause, it being assumed that the proposed operation would not add much to the already existing danger. This view of such cases I believe to be the right one in the present state of our knowledge of abdominal surgery, and the well-known high rate of mortality in penetrating wounds of the abdomen.

CASE XIII. Massachusetts General Hospital. Closure of the abdominal cavity after laceration of its walls and protrusion of the intestines. Girl, age five. This little girl was run over by a herdic shortly before being brought to the hospital. There was a fracture of the pelvis, laceration of the vaginal wall from the cervix of the uterus to the spine of the pubes. The intestines protruded through the vagina and up on to the groin. The symphysis pubis was fractured, and the bones separated. The bowels were replaced, and the vaginal wound closed with catgut. The pubic bones were wired together. The mother refused to leave the child at the hospital, and she was treated as an out-patient. She made a rapid recovery, however, and some weeks later I removed the wire, and found the vaginal wound healed and the child nearly well.

LAPAROTOMY FOR DIAGNOSIS IN SUSPECTED TUMOR.

CASE XIV. A woman of thirty-eight had been much troubled by enlargement of the abdomen for five years. She was admitted to the Carney Hospital in the spring of 1884, and was treated on the medical side for some weeks. Several careful examinations were made, including two under ether, but nothing abnormal could be found. At her urgent request, and with the advice and consent of the attending physicians the abdominal cavity was opened and explored. January 25, 1885, an incision was made in the linea alba large enough to admit the hand. The abdominal organs were examined successively with care, and nothing was found requiring operation. She made a

[2] See page 567 of No. 24, Vol. CXV of this Journal.

rapid and uninterrupted recovery, and for a time expressed herself as feeling much better than before. She was discharged, however, unimproved.

LAPAROTOMY FOR THE REMOVAL OF UTERINE TUMOR.

CASE XV. Patient age forty. History of an enlargement of the abdomen of a year and a half. The enlargement was at first slow, and later it has been rapid. Catamenia regular. Examination of the patient showed a large symmetrical tumor of the abdomen, not painful or tender. At my first examination there seemed to me to be distinct fluctuation, and I made the diagnosis of a simple cyst of the ovary. The uterus moved with the mass but did not seem to be intimately connected with it. The whole mass could be pushed up with ease from the pelvis with the hand in the vagina. The general health of the patient was not much affected, and the case looked extremely promising. March 14th, Dr. Fitz examined her with me and threw some doubt on my diagnosis, saying that the tumor did not have the unmistakable fluctuation of a cyst. It suggested a semi-fluid contents, or possibly a soft fibroid.

Operation, March 15th. Carney Hospital. An incision three inches in length was made in the linea alba, and the tumor exposed. It was found to be fluctuating, and was supposed of course to contain fluid. The introduction of the trocar was not followed by escape of fluid, and the tumor was then seen to be solid. The incision was then enlarged to six inches and the tumor delivered. The pedicle was pierced with two knitting-needles at right angles to each other, and ligated below with elastic tubing. In cutting off the tumor the uterine cavity was not opened. The tumor arose from the posterior wall of the uterus, and there was no real pedicle, the whole having the appearance of an enlarged and symmetrical uterus. There was a

very large bloodvessel in the left broad ligament, which was tied and burned, as it seemed to be the main arterial supply to the tumor. In applying the ligature to the pedicle use was made of a pair of enormous double hooks made for the purpose, by means of which, through a tackle and blocks, the tumor was held suspended from the ceiling sufficiently to allow the manipulations at the base of the tumor without interference from its size and weight. During this part of the operation the intestines escaped from the wound, very unfortunately, and were exposed eight minutes to the air, although covered with a carbolized towel. It was found extremely difficult to replace them on account of the tight contraction of the abdominal muscles. The incision was carefully closed about the pedicle and the wound dressed with iodoform and gauze in the usual manner. The operation lasted forty-five minutes. The tumor was pronounced by Dr. Fitz to be a lymphangiectatic fibromyoma.

During the following days the most troublesome symptom was vomiting and flatulence, much gas escaping from the mouth. Nothing whatever passed rectum. The temperature gradually rose from 101° the first night to 104° the night of her death, which took place March 19th. The abdomen became very much distended, and vomiting was incessant. The question whether there was some obstruction to the intestine was constantly in my mind, but the impossibility of making a diagnosis between that and a general peritonitis, with the experience of others in such cases, led me to delay in the hope that nature would unravel the difficulty, and especially from the fact that reopening the abdomen in such cases has been almost invariably fatal. Moreover, many recoveries have followed where the symptoms were fully as bad as in this case. I therefore did not interfere till the last day, when I explored the wound and the parts immediately subjacent without finding anything to be remedied. At this time the patient was moribund. Death took place the same night.

My assistant made an examination shortly after death (twenty minutes), and gave me the following report, which I was unable to verify, having been called away for two days.

"The abdominal wound was enlarged up to the ensiform cartilage and downwards to the pubes. An examination of the intestines showed a twist in the gut about the middle of the small intestine. Below the twist the intestines were entirely collapsed, and above were distended with gas. At the point of stricture the intestine seemed to be twisted upon itself, and was black and gangrenous, extending above and below about four inches, gradually fading to the normal of the rest of the intestines. There was no pus in the abdominal cavity, and no opening into the intestine could be discovered."

This condition could have been remedied, of course, had it been possible to make a correct diagnosis. The difficulties in the way of such a diagnosis are certainly very great, and the fact that cases recover after these severe symptoms have been present some days make one much more reluctant to interfere than he might otherwise be. I do not see how this could have been avoided, and I am sure if I was to repeat the operation under the same circumstances I should use the same precautions in replacing the bowels that I did in this case with such disastrous consequences. It is very important that the intestines should be restrained from escaping, and I think that hereafter I shall have an assistant whose sole duty shall be to prevent such an occurrence.

PLEURISY WITH EFFUSION.[1]

BY THOMAS F. SHERMAN, M.D.,
Physician Boston Dispensary.

I BRING the following cases of pleurisy with effusion before the Society to-night, not with the expectation of adding anything to the knowledge which the members may already possess, but rather in the hopes of being myself instructed, in the discussion of the paper, as to the efficacy of the usual routine treatment of effusions, and as to the proper time in the course of the disease when operative interference shall be deemed advisable, whether aspiration should be performed, as some authors advise, as soon as physical examination can detect an effusion, or is to be regarded, like tracheotomy, as a *dernier resort* in cases where danger to life is imminent.

CASE I. In January, 1884, I was called to see Mary D., aged five years, and obtained from her mother the following history. She had always been a healthy child up to a year ago, when she had broncho-pneumonia following measles; since then she has been well till during the last four weeks, when her mother noticed that she was losing flesh and was unable to run or talk fast owing to shortness of breath; she has had a dry hacking cough, and has been feverish at night.

Physical examination showed a poorly nourished child with flatness on percussion, below the level of third rib, over the left front and axillary region, and below the spine of scapula behind, with absence of respiratory sounds and vocal fremitus. The apex of heart was displaced one inch to the right of mid-sternum. Pulse 132, respirations 40, and temperature 101°.

She was kept in bed, fly blisters applied to the lower part of left back, and three grains of the iodide of potassium given every four hours.

This treatment was followed for four days without producing any improvement in either the rational or physical signs. Believing that the effusion had already lasted three weeks, or more, and that it would not be prudent to allow it to remain longer, on January 28th, I punctured, first with my exploring needle attached to a hypodermic syringe, and then with the aspirating needle, one inch below the angle of scapula and drew off a pint of clear sero-fibrinous fluid. She was then given half a teaspoonful of the camphorated tincture of opium to relieve coughing. The next day the child was very comfortable, the apex of heart was almost back in normal position, and there was good resonance and respiration in front as low as nipple; behind there was still flatness and absence of respiration below the angle of scapula. She was ordered the tincture of chloride of iron and malt extract, and continued to improve uninterruptedly, although it was two months before there was good resonance and audible breath sounds below the angle of scapula.

I saw her one week ago and she was still in good health, and no abnormal sounds were found in chest by auscultation or percussion.

[1] Read before the Boston Society for Medical Observation, April 4, 1887.

Case II. Miss R., aged thirty, attributes her present illness, which began two weeks before I saw her, to exposure while taking in clothes during a rain. When I first saw her, February 9, 1884, she had been in bed a week, complaining of pain on inspiration over right side, less severe then than at first, shortness of breath, cough, with whitish expectoration, loss of appetite, alternate flashes of heat and cold, no chill.

Physical examination showed the presence of a bronchitis with a moderate effusion on the right side. Pulse 105, temperature 102°, respiration 26. She was given the iodide of potassium, ten grains four times a day, with the extract of elaterium, an eighth of a grain every two hours till free dejections. The next day she was feeling more comfortable, had had numerous watery dejections and was breathing much easier. On February 12th, fair respiration was heard over the whole of right front and over the right back to an inch below the angle of the scapula. She continued to improve till February 15th, when being disturbed by a blind rattling in the night, she imprudently got up, fixed the blind, and then went back to bed again, feeling cold and chilly.

On seeing her the next afternoon I found her much worse, and physical examination on the day following showed flatness over the right front and axillary regions, below second rib, with bronchial respiration and bronchophony under the right clavicle.

Apex of heart was one inch beyond the mammary line, edge of liver felt below the ribs. Pulse 112, respiration 34, temperature 102°.

The extract of elaterium was ordered as before, but this time did not cause any diminution in the effusion.

On February 18th, the physical signs remaining the same, I aspirated below angle of scapula and drew off two quarts of clear fluid, without trouble. That evening I was suddenly called to see her and found her breathing at the rate of fifty per minute, respirations shallow and painful, physical examination showed no return of the effusion, and on injecting an eighth of a grain morphine, subcutaneously, the respirations soon fell to thirty per minute, and she spent the rest of the night very comfortably. She had no further trouble after this, the temperature, pulse, and respiration gradually falling till they became normal in about five days. She has been in good health since then up to the present time.

If we are to consider in this case and in Case I that the pleurisy was not a disease *per se*, but a symptom of tuberculosis, as some German writers maintain, it would seem that in three years other symptoms should arise, or, as Dr. Shattuck has said, that tuberculosis is recovered from more frequently than is commonly supposed.

Case III. B. M. was a stout, well-built man, aged twenty-eight, of good family history, and a blacksmith by trade. He says he has never known what it was to be sick, and now consults a doctor for the first time, to be relieved, if possible, of a shortness of breath, which has been gradually increasing during the last three weeks, till he is unable to swing his hammer without getting out of breath, and having to rest afterwards. His appetite is poor. He has a slight, dry cough. Has not been confined to his bed, and has worked up to two days before I saw him.

Physical examination showed the presence of a large effusion on the left side, extending anteriorly above level of third rib, and behind to an inch above spine of scapula. The left intercostal spaces were bulging, with apex of heart almost two inches to the right of sternum. Temperature 99°, pulse 90 and intermittent; respirations 34 to the minute when he was quiet, but becoming rapid on the least exertion.

Feeling that this was a case where the heart was impeded in its work by the amount of the effusion, and that any delay might prove dangerous through sudden paralysis of the heart, I made arrangements to see him later in the day, when I slowly removed, by aspiration, a little over three pints of clear serum before I was compelled to desist by his complaining of a feeling of constriction across the chest. He was given brandy, and the carbonate of ammonia ordered in ten-grain doses, every four hours. The next day the heart was beating regularly, with the apex mid-sternum, and in about a week later, he was able to return to his work.

Case IV. H. D., aged nineteen, clerk, was seen in January, 1885. He had been complaining for a month of progressive loss of flesh and strength, with shortness of breath on exertion. His family history was good.

On examination, a large effusion was found occupying two-thirds of left chest, with apex-beat to the right of mid-sternum. During the next three days he was given the iodide of potassium, and the back painted with tincture of iodine morning and night.

The effusion showing no signs of being absorbed, I then punctured the chest twice with the aspirating needle, the first time unsuccessfully, owing probably to the puncture being made too low down, the second time withdrawing about a quart of fluid. The rest of the effusion disappeared in the course of a week, and he soon afterwards returned to his work. I saw no more of him for five months, when he again appeared at the office, complaining of the same symptoms as before. Examination this time, however, showed well-marked disease at left apex, which ended fatally in about three months. In this case, the pleurisy was probably only a symptom of tuberculosis, although I believe that it is now admitted that a long-continued effusion may indirectly cause lung disease, as well as be produced by it.

Case V. On December 17, 1886, I was called to see Mrs. M., aged twenty-eight, who gave the following history: She had always been well up to four days ago, when she got her feet and clothes wet. Since then she has felt cold and chilly, with headache and general malaise. The day before I saw her she had had a chill in the afternoon, followed by a second one at night. Has had a dry cough, with pain under right nipple. Examination showed diminished resonance over the lower right back and axillary region, with feeble respiration; no râles. Temperature 102°, pulse 110, respirations 26.

Dover's powder ordered at night. The next day she reported that she had rested well. Examination showed flatness and absence of respiration below angle of scapula posteriorly, and below fifth rib anteriorly. During the next week the effusion increased gradually, with slightly higher temperature at night, till, on December 27th, ten days after I had first seen her, it had reached the third rib in front, and the spine of scapula behind. The apex of heart was outside of the mammary line. Measurement of the left side, from centre of sternum to the centre of spine, was fifteen inches; of the right side, sixteen inches.

The treatment up to this time had been mainly expectant, liquor ammonii acetatis being given during the day, with Dover's powder, when required, at night. On December 27th, patient had three watery dejections, and, believing that nature was thus indicating an outlet for the effusion, I ordered her to take half an ounce of epsom salts, dissolved in as little water as possible, the first thing the next morning — the treatment laid down by Professor Hay. This produced twelve loose dejections, which left the patient feeling weak, but breathing much easier, the respirations falling from 34 to 24 per minute, and the apex of heart swinging back almost to its normal position.

From this time on there was an improvement in all the signs, till January 8th, a little over three weeks from her first attack, when she was able to go out. At this time, there was still dulness and diminished respiration over the lower half of the right back, due, probably, to the thickened pleura.

From the above cases, and from the numerous authorities whom I have consulted, and to whom I am indebted, I would draw the following conclusions:

That acute pleurisy with effusion runs a certain more or less definite course, and cannot be aborted by any of the remedies now in use; and that the treatment, during the first ten or twelve days of the disease, should be purely symptomatic, including, by that term, the use of the aspirator, if required, as well as the administration of drugs.

At the end of that time, when the effusion seems to have reached its height, and the fever is beginning to abate, the treatment by saline cathartics, first introduced by Professor Hay, and recently recommended by Professor Osler, seems to be the most successful. This treatment consists in giving a concentrated solution of the salt at such a time when the intestinal canal may be supposed to contain little, if any, fluid. The usual plan is to tell the patient to take nothing liquid after supper, and to take, the first thing the next morning, about half an ounce of the sulphate of magnesia, dissolved in an ounce of water, and not to drink anything afterwards till dinner. This usually causes numerous watery dejections, with a subsequent diminution in the amount of the effusion. Should this not be the result, I would order an ounce of the magnesia, to be taken the next morning. Should the effusion still remain the same, I would aspirate without further delay.

In cases of chronic effusion, if no urgent symptoms were present, as marked dyspnœa, cyanosis, irregular or very feeble pulse, I would try the saline cathartics first, and then aspiration.

I believe that every case of pleurisy with effusion should be watched as carefully as we do a pregnant woman with placenta prævia, having the aspirator in working order, and ready for use at an instant's notice, bearing in mind that any effusion, large or small, is bad for the patient, and may suddenly become dangerous with but little warning, while aspiration, thanks to Dr. Bowditch, has been proved to be harmless.

As there are no signs of an effusion which may not be simulated by other morbid conditions of the chest, and this is especially true in children, where physical examination is often misleading, owing to imperfect lung-expansion, every aspiration should be preceded by an exploratory puncture, using the ordinary hypodermic syringe, with a long, stiff needle, to avoid the danger of its breaking within the chest.

In these days of bacilli and micrococci, it would be needless to say that all instruments should be properly disinfected before using, thus avoiding many of the dangers formerly ascribed to the admission of air within the chest.

The aspiration, as Dr. Bowditch has taught, should be slow and gradual, not removing more than two or three pints at a time, and ceasing at once when the patient complains of any distress. It should be performed without ether, the puncture being made below the angle of the scapula, or in the middle axillary region, with the patient in a sitting position, unless there is cardiac weakness, when the recumbent position is to be preferred.

The dangers commonly ascribed to aspiration come, I believe, either from its being improperly performed, or from its being too long deferred. With proper precautions, I know of no contraindication to its employment. The reflex paroxysmal coughing often following aspiration may be relieved by an injection of morphine subcutaneously.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

APRIL 4, 1887, DR. BOLLES in the chair.

DR. M. H. RICHARDSON presented a paper upon

A SERIES OF ABDOMINAL OPERATIONS.[1]

DR. MIXTER thought the entire absence of any septic element in these cases was evident. In the last case, the accident might have been due to tenseness of the recti muscles, due to insufficient etherization. The manner of treating the pedicle by an elastic ligature, although common in Germany, was not used here.

DR. FITZ said it was more probable that the twist occurred during reaction than at time of operation, even if it were the cause of death.

DR. DAVENPORT alluded to the success attending cases recently reported, in which thorough evacuations were secured by Seidlitz powder and enemata — a practice directly the opposite from the universal employment of opium.

DR. RICHARDSON thought the length of the incision was not an important factor in fatality. The rule should be to make an incision large enough for easy delivery of the tumor.

DR. NEWELL said that the true source of trouble in cases where the intestines prolapsed was absence of profound anæsthesia. This is the great advantage we possess in the employment of ether, instead of chloroform.

DR. T. F. SHERMAN presented a paper upon

PLEURISY WITH EFFUSION.[2]

DR. FOLSOM advocated the aspirator, rather than cathartics, and an early, rather than late aspiration. With reference to the occurrence of tuberculosis secondarily, he cited two autopsies: one of a lady in middle life, who had double pleurisy, when five years old, on the right side. She was tapped, resulting in

[1] See page 225 of this number of the Journal.
[2] See page 228 of this number of the Journal.

an empyema with permanent opening; on the left, nothing was done. Both *lungs* were sound, but the *pleura* completely adherent. The second case was a lady who, twenty-five years before, had an empyema with permanent opening — a very tedious case, but the lung was perfectly sound.

Dr. Bowditch said that he would not usually wait over a fortnight before aspirating, and if the quantity were large, causing dyspnœa, would aspirate at once.

Dr. Otis said that, as one could not foresee at what moment serious trouble would arise, perhaps fatal, it seemed to him the wiser course to aspirate at once, if the amount were large, without delaying for dangerous symptoms to come on.

Dr. Forster said that his experience showed the rapid recurrence of the fluid after it had been diminished by salts.

Dr. Bowditch said that in his early experience, before days of antisepsis, permanent openings made tedious cases, and often unfavorable results, but he could not admit that simple pleurisies were tubercular. He thought the prognosis was unfavorable if the lung did not fully expand in a few days.

Dr. F. C. Shattuck alluded to the increasing number of German and French authorities who maintain the great rarity, or absolutely deny the existence, of pleurisy as a primary disease, holding that the cases which have hitherto been so generally considered as such are really only symptomatic of tuberculosis. This view we are not as yet, certainly, prepared to accept in America. Whether this view is true or not, it is incumbent on us to follow up our cases of pleurisy with effusion carefully, and not consider them as completely recovered as long as expansion of the lung is imperfect — a condition which seems distinctly to predispose to the development of mischief in the lung itself.

He also spoke of a case reported by R. Douglas Powell in the last edition of his book on "Diseases of the Lung and Pleuræ." A London policeman had been the subject of, to his knowledge, a large, serous effusion for five years, and was quite equal to his duties. Tapping had been practised several times, but the fluid promptly re-accumulated, and it was thought wiser to let him alone. If the lung is completely compressed, and is represented by simply a fibrous cake, as would seem to have been the case in this policeman, there is probably less danger of tuberculosis than in the far more frequent cases of partial re-expansion.

Dr. M. H. Richardson said he was particularly interested in that part of the paper which was devoted to the question of removing the effusion by surgical means. He called attention to the importance of thorough disinfection of the needle before its introduction into the pleural cavity. It should not only be carefully washed and soaked in an antiseptic solution immediately before its use, but it is well to draw into the receiving bottle a quantity of antiseptic fluid, and then, having turned the cock, thrust in the needle, now full of fluid itself. Great importance should be given to this disinfection, because the serous effusion is such a good medium for the growth of germs, and, therefore, so liable to become purulent.

With regard to the question of tuberculosis as a cause of all cases of pleurisy, the experience of the speaker clinically was that a direct family history of tuberculosis in the patient's near relative always rendered the prognosis extremely doubtful as far as the expansion of the lung was concerned. Without an exception, the lung has failed to expand after the operation of permanent opening has been done, if there was any such family tendency. It was his experience that such cases run more frequently from a pleurisy into an empyema, and never fully recover, than after permanent opening, unless the operation is supplemented by others for the collapse of the chest-wall (either by the operation of Estlander, Schede, or something similar). Dr. Richardson was convinced that, in certain rare cases, it is best to make free drainage, even where the effusion is serous: First, in a very acute case where the fluid is effused with great rapidity, and after aspirations without relief, the patient is in danger from the violence of the constitutional disturbance; and the other class is where a chronic effusion shows no sign of abatement after repeated tappings. In the latter class, there is the hope that the lung may be made to expand, and thus obliterate the pleural cavity; and, on the other hand, there is the constant danger of secondary changes in the partially-collapsed lung. Yet, in such cases, the prognosis and treatment depend much on the family history.

In the speaker's experience and opinion, the immediate danger of free incision is less than that of aspiration. The reason for this is seen when we consider the difference of pressure in the two operations. In aspiration there is exerted a powerful suction, which affects the thoracic contents without any possibility of a safety-compensation, so to speak. The collapsed lung must expand, or the sound one must become overdistended, and the heart moved correspondingly. In free incision, on the other hand, there is never any pressure brought to bear till the dressings are applied, and then it is very gentle and gradual in its working. The air is all ready to enter and take the place of the escaped fluid the moment the lung has expanded all it will from its own elasticity. Clinically, this is seen in every case of permanent opening, especially when it is done without making the patient unconscious. There has never been any complaint of distress, while it is the rule in aspiration.

AMERICAN DERMATOLOGICAL ASSOCIATION.

Eleventh Annual Meeting.

The Eleventh Annual Meeting of the American Dermatological Association was held in the Hall of the State Medical and Chirurgical Society, Baltimore, August 31, September 1 and 2, 1887.

WEDNESDAY.— FIRST DAY.— MORNING SESSION.

The Association was called to order by the President, Dr. H. G. Piffard, of New York. The first paper was entitled

TOXIC EFFECTS OF IODOFORM,

by Dr. R. W. Taylor, of New York.

The author reported the details of twenty-four cases, nine of which came under his personal observation. Sixteen of these cases were accompanied by constitutional disturbances, while in nine the rash existed alone without any apparent systemic symptom. A large number of cases have been reported in which toxic constitutional effects have followed the use of iodoform. It is evident that the toxic effects of iodoform are more frequently manifested by systemic irri-

tation than in cutaneous manifestations. The drug may set up inflammatory disturbance of the skin without apparent constitutional reaction.

The skin affections may be classed under the general head of dermatitis, but for the sake of accuracy may be further subdivided according to their relative frequency, into erythema, eczema and purpuric spots. The erythema due to iodoform, may present many of the features of similar eruptions. Its mode of invasion is prompt and extension rapid. It may commence at the point where the application has been made, or other patches of erythema may begin in other parts and extend to meet that from the original point. Erythema may follow from simply smelling the iodoform. The eruption completes its evolution in a few days, and under favorable circumstances this eruption rapidly undergoes involution, behaving much as an ordinary exanthematous eruption. Various forms of erythema have been noted. Sometimes it is very superficial. In other cases it is still superficial, but of a deep red hue, and may be termed scarlatiniform. In exceptional cases, usually those presenting grave constitutional symptoms, the erythema presents points of resemblance in hue and brauny feeling, to erysipelas. Other cases may be placed under the head of erythema multiforme.

The eczema resulting from the use of iodoform is usually of severe form and rapid evolution. It may begin at the point of application or in parts at a distance. It may also result from simply smelling the drug. Its character is pronounced from the first. A large surface is involved, and in all respects it is similar to ordinary eczema madidans. The involution is, as a rule, almost as rapid as the evolution, if the drug is removed. In some instances, however, the eruption shows a tendency to become chronic. It is usually amenable to treatment. Eczema occurred in nine of the twenty-five cases reported.

The time of the appearance of the eruption was noted as follows: in twelve cases, it began within a few hours, or within the first day; two, on the second day; three, on the third day; one, on the ninth day; one, on the twelfth day; and two, on the fourteenth day. This is in contrast with the statistics of the onset of the symptoms where systemic poisoning results. In the majority of these cases the morbid symptoms begin in the second week. As a rule, it may be stated that in proportion as the rash is slow in appearing, so are the concomitant symptoms severe. Statistics seem to show that the cutaneous manifestations are most frequent in youth and middle age, while the systemic symptoms occur most frequently in the aged. The erythema appearing upon the hands of dressers in hospitals as a result of the direct contact of the iodoform, was regarded as being related to the ordinary hyperæmia induced by mustard and other irritating applications, and not to be considered as belonging to the class of cases described.

DISCUSSION.

DR. J. N. HYDE, of Chicago. I have seen the eczematous form of eruption, and also erythema multiforme, and in one case a bullous type of eruption resulting from the use of iodoform. This occurred in a young man who had an operation performed for necrosis of the tibia. Iodoform was used in the dressing of the wound. The recovery was complicated with recurrences of erythema upon the surface of the body. This occurred in the form of large areas of a vivid bright color, afterwards becoming dull. Scattered over these surfaces were large bullæ containing a clear transparent fluid, and when ruptured produced superficial excoriated surfaces. The condition was finally traced to the iodoform application, and within ten or twelve days after the discontinuance of the iodoform, the eruption disappeared and did not recur.

I would dismiss from this category all cases in which iodide of potassium is given internally at the time that the iodoform is employed externally. I suspect that in these cases where the eruption occurs, it is due to the iodide of potassium, for we see occasionally cases in which iodide of potassium has been taken for a certain period without unpleasant effects, suddenly present manifestations of iodism as the result of some transitory condition, as change of climate, or of temperature, etc.

DR. J. C. WHITE, of Boston. I have seen a number of cases of eruption due to the free use of iodoform in the treatment of surgical injuries. I have never seen systemic manifestations resulting from its use in cases where there was dermatitis. The form of eruption has varied from simple hyperæmia to a vesicular form, in most cases going no further. In occasional instances there appeared a furuncular form of inflammation, due possibly to mechanical obstruction of the cutaneous follicles by particles of the powder. The eruption is almost always found in the immediate vicinity of the point of application. Where the remedy is applied in the form of a powder, it may easily be transferred to other parts of the body and thus cause an extension of the eruption. I have never seen any affection of the mucous membrane resulting from the use of iodoform, nor have I seen any purpuric eruption follow its use.

DR. R. W. TAYLOR, of New York. With reference to Dr. Hyde's remark in regard to the influence of iodide of potassium in those cases where it was administered in connection with the local application of iodoform, I would state that, in one case seen by me, the eruption came on when the patient was not taking iodide of potassium, and was relieved when the iodide was given. In another case, the patient (a physician) thought that the eruption was worse when he was taking iodide of potassium, but the eruption always promptly followed the use of iodoform, even when no iodide was taken.

A CLINICAL STUDY OF ERYSIPELAS IN CHILDREN,

by DR. I. E. ATKINSON, of Baltimore.

The author considered erysipelas to be a contagious, infectious disease. It has not yet been determined whether it is due to one special micro-organism, or whether it may be produced by several. The study of the affection, as it occurs in children, offers some opportunities for the solution of this question. During the first month erysipelas is extremely fatal, but the mortality gradually diminishes up to the end of the first year. The fatality at this period of life is probably to be attributed to its dependence upon the poison of puerperal fever. The author reported the detailed histories of three cases of erysipelas in young children. In two of these cases a cellular, board-like induration occurred as the result of intense œdema and cellular infiltration. In neither of these cases was there suppuration. The speaker thought

that erysipelas should be considered the expression of the effect of one of a number of specific causes, and, in that sense, should be regarded as a symptomatic inflammation.

DISCUSSION.

Dr. J. C. White, of Boston. The author alluded to erysipelas as a contagious disease. Does he personally know of a case in which it was directly transferred from one person to another? He also referred to the use of the tincture of the chloride of iron in the treatment of the disease; does he regard this as producing any specific therapeutic action?

Dr. I. E. Atkinson. Personally, I have not seen an instance of the direct contagiousness of erysipelas, but there are a number of well-authenticated cases on record. I cannot say that the tincture of the chloride of iron is a specific, but, in my experience, it has had a more favorable influence on the course of the disease than any other remedy that I have employed.

Dr. J. C. White, of Boston. I have never seen a case of facial erysipelas transferred from one individual to another. If at all contagious, it must be so with extreme rarity. I regard the tincture of the chloride of iron and all other internal remedies as useless in the treatment of this form of erysipelas. For five years, I have given no internal medicine in the treatment of erysipelas, and I have not seen a case in which the erysipelatous eruption did not disappear in from five to ten days. In my experience, infantile erysipelas has been so wholly unlike in its clinical aspects and in its course, with or without treatment, from ordinary traumatic erysipelas, that it seems to be quite a distinct disease.

Dr. J. N. Hyde, of Chicago. I have seen one case which seemed to indicate the contagious nature of erysipelas. A young mother, soon after confinement, had her ears pierced for ear-rings. This was shortly followed by typical erysipelas, spreading over the face and scalp. Soon the nursing child was affected with the disease, and presented typical erysipelas, from which it shortly died.

I agree with Dr. White that the tincture of the chloride of iron is useless in the treatment of this affection, although I consider it harmless.

Dr. I. E. Atkinson, of Baltimore. In those cases of erysipelas which may be termed septic, whether the disease depends upon ordinary septic poison or not, I have no doubt that benefit is derived from the administration of the tincture of the chloride of iron in large doses — as much as half-a-drachm, three or four times a day.

LEUCOPATHIA UNGUIUM — A PECULIAR AFFECTION OF THE NAILS,

by Dr. R. B. Morison, of Baltimore.

The ordinary white spots found upon the nails are well known. These are gradually forced to the outer edge of the nail by the growth of new nail behind. The time occupied in this process varies from four to six months. These spots are usually irregular in shape. A young lady, twenty years of age, recently came under the author's observation, in whom these spots presented a uniform appearance. Examination of the nails showed white bands, one-sixteenth of an inch in width, extending across the nail from border to border. The nails were perfectly smooth, and, in other respects, normal. The general health was good, and there had been no acute disease. These white bands across the nail had been regularly appearing for many months. During the previous summer, the lines had disappeared almost entirely. The toe-nails were not affected, and the hair was not gray. Portions of the nails were secured, and subjected to microscopical examination. Sections were made, cutting the white lines at right angles. By direct light, the lines appeared of a pure-white, while the rest of the section was of a dark color. The application of acetic acid and other agents caused a gradual disappearance of the lines. Canada balsam also caused their rapid disappearance. It, therefore, seemed plain that these white lines were due to air-spaces in the nail, the disappearance being caused, in the one case, by the swelling of the adjacent cells, induced by the acetic acid, and in the other, by the filling of the spaces with the Canada balsam. Examination of several white spots gave similar results.

OBSERVATION OF THREE CASES OF SIMULTANEOUS HAND-AND-FOOT-DISEASE,

by Dr. James Nevins Hyde, of Chicago.

Case I. C. B., aged nineteen years, came under observation in May, 1887. Family history was good. He denied all specific disease. Three years previously, he had noticed the first signs of the present affection upon the fingers, and later, on the toes. The disease then extended to the palms of the hands and the soles of the feet. The local affection had gradually increased, and he complained of the stiffness thereby induced. The free border of the nails was tilted away from the finger, and the space thus left was filled with hardened matter. The substance of the nail was dry and rugous. He had recently noticed some sweating of the hands. The palms of the hands and the soles of the feet presented a condition of tylosis. The nails of the toes were tilted from the phalanges, and presented a condition similar to that seen in the nails of the finger. There was also bromidrosis.

Case II. A female, aged twenty-four years. Family history good. The patient presented tylosis of the hands and feet, which continually recurred. Careful examination showed the general condition to be fair. The pulse was unusually slow, being fifty per minute in the sitting posture. The hands were cold, and bathed with profuse perspiration. The finger-nails were somewhat rugous. The nails were tilted from the fingers, and the space filled with grayish masses. The same condition existed in the toe-nails. The palms of the hands and the soles of the feet were simultaneously involved, showing callosities. Every six or eight weeks, there was a reproduction of the masses on the soles of the feet. At no time did the tissues beneath these masses present a sound appearance. Treatment with various measures, continued over a long period, had no apparent effect.

Case III. A male, aged twenty-eight years, with a good family history, and no history of syphilis. For ten years, had noticed some numbness of the lower extremities, especially marked at night. There was entire absence of hair on certain parts of the lower extremities. He stated that, fifteen years before, he had been struck on the head with a brick, and that a few years before coming under observation, an operation had been performed upon the head, the exact nature of which he could not state. The hands and feet were habitually cold. Broad vertical areas, chiefly on the outer aspects of the limbs, were found,

in which not a single filament of hair could be detected. Two of the finger-nails of the right hand showed marked vacuolations.

The above papers were discussed together.

DISCUSSION.

DR. T. A. DUHRING, of Philadelphia. I do not recall a case of white spots upon the nails in which the distribution was as uniform as in the case described by Dr. Morison. I have, however, met with cases calling for treatment. I have regarded the affection as dependent upon a want of nutrition in the nail-tissues, and, with that view, have employed arsenic, with satisfactory results. This acts upon the nervous system, improving the nutrition of the whole system, and of the finger-nails in particular.

DR. P. G. UNNA, of Hamburg. With reference to Dr. Morison's paper, I would say that we know from the labors of various investigators that the presence of air in the horny tissues is always a secondary phenomenon. The horny masses must be changed before they will allow the entrance of air. These white spots in the nails are analogous to medullary substance.

I have seen cases similar to those described by Dr. Hyde where the affection was not one simply of the nails, but also of the hands and feet, and I have allied them with eczema. My principal reason for so doing has been that in some cases, I have seen combined with the disease of the hands, patches of eczema on various portions of the body.

DR. R. W. TAYLOR, of New York. I should regard the cases described by Dr. Hyde as ordinary cases of tylosis of the hands and feet. This may occur idiopathically, without apparent cause; or as a result of chronic eczema or as a result of chronic syphilitic psoriasis.

DR. LE GRAND N. DENSLOW, of St. Paul. I am not in accord with Dr. Hyde in his view of the nature of the cases that he has described. I have regarded such cases as instances of callosities. With reference to treatment, I would say that in my last case in the person of a hotel porter, who was unable to perform his duties on account of the tender condition of the soles of the feet, I first removed the callosities by the application of a saturated solution of salicylic acid in collodion, and then made a false sole for the feet by the application of belladonna plaster spread upon kid. By this means he is able to attend to his work in comfort.

DR. L. D. BUCKLEY, of New York. I have under my care a patient who presents a condition of the nails very similar to that described by Dr. Morison. She is a sufferer from gout, and from her family history I considered that these lines were possibly gouty deposits. I think, however, that Dr. Morison has shown their true nature.

I agree with Dr. Taylor in considering the cases reported by Dr. Hyde, as closely allied in their nature to cases of eczema. In the treatment of these cases I have derived considerable benefit from keeping the part constantly macerated by the use of an oiled-silk lining sewed into an ordinary stocking and worn constantly, night and day.

DR. E. WIGGLESWORTH, of Boston. I have now under treatment, a case similar to those described by Dr. Hyde. I have regarded it as a case of tylosis. In the treatment, I have employed a twenty per cent. solution of salicylic acid in soap-plaster until the callosities were removed. I have then dressed the parts with equal parts of belladonna and mercurial plaster, spread on kid. Regarding the condition as dependent upon lowered nutrition, I also employed tonics with good effect.

DR. G. H. TILDEN, of Boston. In connection with Dr. Morison's paper, I would mention a case which I recently saw. It was an instance of two nails growing on one finger, one above the other. The patient had one year ago met with an accident which destroyed the nail and evidently split the matrix into two halves, and each half of the matrix had produced a separate nail.

The President, DR. H. G. PIFFARD, of New York. The affection described by Dr. Morison, is one which in its mildest form, we are all more or less familiar. The most aggravated case that I have seen has come under observation within the last two weeks. This case presents fully as extensive leucopathies as the case reported to-day, although not so regularly distributed. This condition is analogous to leucopathia of the hair, in which I have satisfied myself that the condition is due to fatty degeneration of the cells and subsequent absorption of the fat. In the case of the nail after the absorption of the cells which had undergone fatty degeneration, the horny nature of the tissue would prevent closure of the cavity which would remain filled with air.

DR. J. N. HYDE, of Chicago. I would merely state that like Dr. Taylor and Dr. Bulkley, I first regarded these cases as instances of tylosis, but a large experience showed that this view was not correct. In one case, I have watched the course of the disease for three years. The parts have been macerated for days and weeks at a time. I know that there is a constant new formation of these masses. I know that the nails are continually undergoing a similar process. These cases are entirely different from the ordinary forms of tylosis and callosities.

(To be continued.)

[Special Report for the JOURNAL.]

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

FIRST DAY.— MONDAY, SEPTEMBER 5TH.

THE Ninth International Medical Congress, and the first of the series ever held in this country, began its sessions in Washington, D. C., Monday, September 5th. The first suggestion of these gatherings was made at the annual meeting of the French Medical Congress in 1865, and the first of the series was accordingly held in Paris in 1867 during the French Exposition with an attendance of 1,200. The second was held at Florence in 1869, but there were only 357 present. The third was held at Vienna, during the Exposition of 1873, and attracted 671 members of the profession. The fourth was held at Brussels in 1875, with an attendance of 412. The fifth occurred at Geneva in 1877 with only 365 present. At the sixth, in Amsterdam, in 1879, there were 630. The seventh was a notable assemblage of 3,181 persons, and was held in London in 1881. The last one was held in Copenhagen in 1884, with an attendance of 1,350.

GENERAL SESSIONS.— FIRST DAY.

The proceedings of the present occasion were begun in Albaugh's Opera House, a very comfortable and pleasant hall, at 11 A.M., Monday, September 5th. The house was packed, the floor with members of the Congress, and the galleries with interested spectators, among whom were many ladies. Dr. H. H. Smith, of Philadelphia, Chairman of the Executive Committee, called the meeting to order and introduced the President of the United States, who was greeted with enthusiastic applause. President Cleveland, in the following few words, uttered with much distinctness and dignity, formally declared the Congress open:

"I feel that the country should be congratulated to-day upon the presence at our capital of so many of our own citizens and those representing foreign countries, who have distinguished themselves in the science of medicine, and are devoted to its further progress. My duty in this connection is a very pleasant and a very brief one. It is simply to declare that the Ninth International Medical Congress is now open for organization and for the transaction of business."

Dr. Smith then read a list of officers of the Congress, who were unanimously elected, the President, DR. NATHAN S. DAVIS, of Chicago, editor of the Journal of the American Medical Association, then taking the chair. The Vice-Presidents numbered eighty. Other officers were as follows: Secretary-general, Dr. John B. Hamilton, of Washington, Supervising Surgeon-General of the United States Marine-Hospital Service; Treasurer, Dr. E. S. F. Arnold, of Newport, R. I.; Chairman of Finance Committee, Dr. Richard J. Dunglison, of Philadelphia; Associate Secretaries, Dr. William B. Atkinson, of Philadelphia, Dr. George B. Harrison, of Washington, Dr. Frank Banga, of Chicago.

The following gentlemen were then elected as Presidents of the eighteen Sections, into which the Congress is divided:

General medicine, Abram B. Arnold, Baltimore; general surgery, Wm. T. Briggs, Nashville, Tenn.; military and naval surgery and medicine, Henry H. Smith, LL.D., Philadelphia; obstetrics, DeLaskie Miller, Ph.D., Chicago, Ill.; gynæcology, H. O. Marcy, Boston; therapeutics and materia medica, Traill Green, Easton, Pa.; anatomy, Wm. H. Pancoast, Philadelphia; physiology, Jno. H. Callender, Nashville, Tenn.; pathology, Alonzo B. Palmer, LL.D., Ann Arbor, Mich.; diseases of children, J. Lewis Smith, New York; ophthalmology, J. J. Chisholm, Baltimore; otology, S. J. Jones, LL.D., Chicago; laryngology, W. H. Daly, Pittsburgh; dermatology and syphilography, A. R. Robinson, New York; public and international hygiene, Jos. Jones, New Orleans; medical climatology and demography, Albert L. Gihon, Medical Director United States Navy; psychological medicine and nervous diseases, J. R. Andrews, Buffalo, N. Y.; dental and oral surgery, Jonathan Taft, Cincinnati.

Each Section was also equipped with a formidable list of vice-presidents, secretaries, and councillors, which the Secretary-General begged to be excused from reading, and they were taken on trust.

The Secretary-General was then called on for his report, and in response made the following statement of the circumstances attending the formation of this Congress.

He said that it was now a matter of history that in May, 1884, the American Medical Association met in this capital and passed a resolution inviting the Congress to honor America by holding its next session in the United States. At the meeting in Copenhagen, when the question came up for disposition, Washington was selected. The committee having borne the invitation and secured its acceptance returned home and immediately began the work of organization. Shortly before the meeting of the American Medical Association in New Orleans, in May, 1885, the preliminary organization was completed. But it transpired that this committee was unable to form an organization satisfactory to the majority of the members of the Association and after some discussion a resolution was adopted, which authorized the appointment of additional members of the committee, so as to include, in accordance with our American system of representation, one member from each State and Territory, and to these were added one representative from each of the three public medical services. The enlarged committee met in Chicago and a majority of the first committee was present and acted harmoniously with the new committee. In a short time, however, the members of the original committee withdrew and the management was thus deprived of their valued services.

The committee had, therefore, to contend against more than the ordinary difficulties attending so great an undertaking, and its success was due entirely to the zeal and energy of its Chairman, Prof. H. H. Smith, of Philadelphia, and the unflagging interest and industry of the remaining members. The time was too short to adequately speak of the multifarious labors attached to the office of the Secretary-general, but he had to report that at the present moment there remained no unfinished business on the Secretary's table. The work of organization was now complete, and he submitted the programme and the volume of abstracts.

President Davis then introduced the Hon. Thomas F. Bayard, Secretary of State, who made a very good address of welcome. After the usual introductory formalities Mr. Bayard happily continued as follows:

"If letters be a republic, surely science is a democracy, penetrated by no royal road, but open on all sides, and equally to all people who, with humility and intelligence, shall watch and work for light as it is gradually disclosed by Divine Providence for human amelioration. In this democratic republic the brotherhood of science can best realize its importance, for here you will find institutions for the promotion of science in every department, and in none more conspicuously than in that of medicine and surgery, the most important of which are the voluntary gifts of private citizens, who, in the great majority of cases, were painfully limited in their associations with science and letters, who began life at the lowest round of fortune's ladder. Thanks, however, to their energy, they rose without a bar to the highest level of success and usefulness. To the public spirit and benevolence of such individuals is due the endowment on a scale which princes may envy but have never surpassed, of institutions for the intellectual development of all who desire to share and are competent to receive its benefits. Your Congress, gentlemen, is held in the closing year of the first century of our national existence, and what has been done here in the line of educa-

tional equipment is due very little to government assistance. To no system of prescriptive privilege, but to individual enterprise, energy and generosity do we owe what, under God, we now possess of such thing, and non-interference by the government has proved a promotion and not a hindrance to our advancement. We are, however, by no means indifferent to the claims of humanity, nor wanting in respect to the victories of science. We welcome this Congress as the guardians of the sanitation of the nations. In your profession, we recognize the noblest school of human usefulness, and in the presence of the development of the means of cure, the amelioration of suffering, the prolongation of human existence, the endeavor to discover the true principles by which life can be made worth living, we can learn our duties to those whose reward is the still small voice of an approving conscience and the sense of duty accomplished."

The following were the closing sentences:

"The closer relations of mankind which modern invention has induced has been necessarily accompanied by an increased dissemination of disease, and the need is obvious of frequent international conference, that, in the grand sweep of scientific observation, new discoveries in the healing art may be promptly tested and applied in counteraction. Forgive me if, as one of the great army of patients, I humbly petition the profession that in your deliberations nature may be allowed a hearing when remedies are proposed; that her *vis medicatrix* may not be omitted in computing the forces of cure, and that science may be restricted as often as possible to sounding the alarm for nature to hasten, as she surely will, if permitted, to the defense of the point assailed. My duty is very simple, and I fear I have already overstepped its limit, for there was, indeed, little more for me to say than to repeat the words of an ancient dame, whose cottage was close by the battlefield of Waterloo, and being somewhat deaf, and hearing the sound of the artillery when the famous 'pounding' was hardest, thought she heard some one knocking at her door, and simply said, 'Come in!' This may seem an unscientific illustration of auscultation and percussion, but you need not make half the noise of Wellington or Bonaparte, and I can assure you the American people will hear you and heartily say to you, as I do for them, 'Come in!'"

Secretary Bayard's address was followed by responses from several representatives of foreign nations,— Dr. William H. Lloyd, of the British Navy; Dr. Leon le Fort, of Paris, read and spoke in French; Prof. Unna, of Germany, in his native tongue; Prof. Semmola, of Italy, who spoke in Italian; and Dr. Charles Rehrer, of St. Petersburg, who confined himself to broken English.

DR. DAVIS then delivered a lengthy address, taking for his chief thought the important benefits in advancing medical science and saving human life through the instrumentality of our medical society organizations, and the methods by which they may be accomplished.

"It has been tersely and correctly stated," he said in conclusion, "that associated action constitutes the characteristic and predominating power of the age in which we live. It is by associated action that education in its broadest sense, religion, and civilization have been more rapidly diffused among the masses of mankind during the present century than during any other period of the world's history.

"It is by the association of capital, wielded by the associated intellects of the nineteenth century, that highways of commerce have been opened over the valleys, through the mountains, across the deserts, and on the oceans, over some of which the material productions of the nations are borne by the resistless power of steam, and along others the products of mental action are moved with the speed of electric currents, until both time and space are so far nullified that the most distant nations have become neighbors, and the inhabitants hold daily converse with each other from opposite sides of the globe.

"Indeed, it is only by means of such of these highways as have been constructed within the memory of him who addresses you, that you have been gathered in this hall from the four quarters of the earth, and through which an account of your doings may be daily transmitted to your most distant homes.

"I congratulate you on the fact that the profession you represent has taken the lead of all other professions or classes of men, in rendering available these grand material achievements of the age, for cultivating fraternal relations, developing and interchanging knowledge, and planning concerted action for rendering human life everywhere healthier, happier, and of longer duration."

This concluded the forenoon's exercises, and the Congress adjourned until Tuesday, the sections meeting by themselves Monday afternoon, in various parts of the city.

SECOND DAY. — TUESDAY, SEPTEMBER 6th.

The Congress reassembled on Tuesday in the Opera House, there being a large audience of members present, though spectators were much fewer than on the day before. Dr. Austin Flint, of New York, delivered a paper upon "Fever, its Causes, Mechanism, and Rational Treatment," which occupied over an hour. Dr. Flint began by explaining the mechanism of normal heat-productions in the body and then went on to consider how it was affected by the processes of fever. He formulated his conclusions somewhat as follows:

That fevers, in general, are self-limited processes probably due to micro-organisms; that the operation of the causes cannot be prevented but can be modified; that the ataxic symptoms in fevers are secondary to the fever itself; that the use of antipyretic measures internally and externally, improves the condition of the patient; that the pyrexia is accompanied by increased oxidation of tissue without compensation; that therefore alimentation, to make up for the increased oxidation, is the essential thing in treatment; that alcohol is an admirable means of nutrition to this end; that, briefly, while the self-limited pyrexia continues, the chief aim of the physician should be to modify its height by antipyretics to afford the system all possible nutrition.

Dr. Flint's paper was well written and well delivered, and kept the attention of the audience to the end. It was the only paper of the day before the general session, and at its close the meeting was adjourned until the next day.

THIRD DAY. — WEDNESDAY, SEPTEMBER 7th.

A much smaller audience was called to order by President Davis in the Opera House, Wednesday morning. The only paper of the session was deliv-

ered by Dr. Mariano Semmola, of Naples, Italy, on "Bacteriology and its Therapeutical Relations." In compliment to his native country, Dr. Francesco Durante, one of the vice-presidents from Italy, was invited to the chair, the trouble which arose as to the proper representative of Italy on the first day, having been apparently smoothed over. Dr. Semmola's address was quite long, and was delivered in French.

The object of medicine, Prof. Semmola said, is to cure disease. If there were no ills there would be no doctors. To cure diseases we must know the causes that produce them. The external causes are visible and tangible. To discover the internal, invisible causes is the aim of medical science. To solve this problem we must employ the true method of solving all problems—before the experimental method was known doctors lost themselves in fantastic speculations. Upon the discovery of the experimental method serious study began. The marvelous progress of physiology was made in the light of experimental methods. When they had studied the morbid condition, the doctors, instead of going on with the same careful and slow research, wanted to hurry on, because they wanted to cure the sick. But to apply the experimental method and, at the same time, go fast, is in the nature of things impossible. So it happened that while the doctors were making experiments in their laboratory instead of having patience to master these studies, they came at once to a conclusion. They had to make new hypotheses, and without knowing it they began again the same errors that had characterized the medicine of an earlier day. Thus new systems came into the field which were the opposite of the experimental method. If medicine is to progress and be a science it must not leave the experimental method, otherwise there can be nothing but renovations of error and loss of time. Like the labors of Sisyphus, the same errors are repeated without knowing it. The error of the day, Prof. Semmola said, is bacteriology considered as the key to all pathology. Bacteriology should be studied, because it teaches us things in the microscopical world of the existence of which we had never dreamed — a microscopical world in which man lives, and which is filled with enemies of mankind. We drink millions of microbes in water and respire millions in the air. Sometimes these microbes affect us; sometimes killing us in a few hours. When it becomes our duty to cure the sick we must go slowly, because before there has been careful demonstration, if we attempt to deduce a remedy, we are in danger of doing harm to the sick instead of curing them. This is the great harm modern bacteriology does. The doctors at once concluded that the microbes were the cause of the disease, whereas, in many cases, the microbes are but the effects of the disease. We ought to reproduce the disease artificially by this microbe before concluding that it is the cause. The experiments made have not given any satisfactory results, except in anthrax and tuberculosis. Then to conclude hastily that this or that microbe in such and such a disease is the cause, is but to ignore or set aside the experimental method. The demonstration which the experimental method demands in this case would be complicated, because we would not only have to know that the microbe existed, but we would have to know what was the condition of the blood necessary to the culture of that particular microbe, and science tells us that, for the present, this is a problem we cannot solve.

We know very little of the normal condition of the blood, and biological chemistry is still in its infancy. Man cannot separate himself from these millions of parasites among whom he lives. That bacteriology may be a guide in the cure of disease, we must not only learn all we can of the microbe itself, but, more important than all, must ascertain all that is possible of the conditions of the field of culture. But the science of the present knows nothing of the conditions of these fields of culture in living organisms. Thus it is evident that in the present condition of bacteriology, it cannot be taken as a guide for the treatment of internal diseases. The older schools of medicine spoke of organic dispositions, or tendencies to such and such a disease. This expression had no meaning, but it expressed the fact. When bacteriology speaks of a need for a special field of culture it says the same thing, because we do not know of what the field of culture consists. Therefore, this cannot be called a science, because a science is never composed of unknown things: it goes from the known to the unknown. Science must indicate to us perfectly the conditions of the phenomena of disease, and then only can we find a remedy to correspond. Medicine must do the same as physiology, chemistry and physics, and proceed by way of experiments and demonstrated facts. Look at the progress made by physics and chemistry applied to industries. Look at the telegraph, the telephone, the steam-engine, the photograph, etc. The experiments which led to these results were not composed of unknown things and hypotheses, but made up of a chain of which the links were perfectly forged and welded. Thus there is no weak link in the chain, and the phenomena produced by the laws of science are at man's disposal, and can be reproduced at his pleasure.

But he does not command nature; he obeys, learns her laws, and respects them. If he supposes a fact, instead of demonstrating it, the phenomena are not reproduced. When he resorts to hypotheses, the power of man disappears. If nature's laws are not respected, the telephone does not work, the electric light does not flash, the steam-engine stops. The doctor, then, is the only one who pretends to become the master of nature without knowing her laws. Referring, again, to the failure of medicine to follow up a discovery in the scientific way with thorough research and demonstration, and its tendency to accept conclusions quickly, Professor Semmola said that modern bacteriology may lead the way to the most fruitful field of inquiry in the future, but, for the present, it has produced no practical results in the cure of internal diseases. It has not, he claimed, been demonstrated in what measure microbes are the causes of diseases. He, therefore, hoped that the younger generation would continue experimental researches with the thoroughness of method which the great masters have transmitted to us. They must renounce their preconceived ideas in medicine, and interrogate nature, without torturing her. Scientific independence must be preserved. They must not proceed without measuring their steps. He trusted that this desire for scientific independence in such researches would be echoed in this land of independence.

At the conclusion of the address, a vote of thanks was extended to Dr. Semmola, seconded by several delegates on the stage, who made very complimentary references to the value and interest of the address.

This completed the exercises of the general session until Thursday.

MONDAY, SEPTEMBER 5TH.

SECTION OF GENERAL MEDICINE.

This body was called to order Monday afternoon, in the chapel of one of the Congregational churches, by the President, DR. A. B. ARNOLD, of Baltimore, about sixty physicians being present. Dr. Arnold then delivered an address upon

THE PRACTICE OF MEDICINE AT THE PRESENT DAY.

He began by saying that the advance in pathological study had brought with it the result of turning the later-day students into medical scepticism and Nihilism, since therapeutic measures seemed futile to arrest the degenerations the scalpel exposed; and many practices, formerly common in the treatment of disease, had now fallen into disuse. And yet, the speaker insisted, the medical profession still had the power to avert many dangers, to relieve much suffering, and to assist nature, if not to cure disease. In acute febrile diseases, if anywhere, there should be therapeutic unanimity, and yet there were as many methods of treatment as nations. The speaker then took up the treatment of typhoid fever as a type of acute disease, and advised the abstraction of heat by external measures as probably the best treatment. In many diseases, the expectant plan remains the best, and preventive medicine offers a wide field. In spite of advance in certain lines of medical thought, the physician of to-day must continue, as his predecessors did, to treat symptoms, in default of his ability to remove causes. Medicine is still rich in facts, but poor in wise theory. Etiology remains the most obscure chapter in the history of medicine, and medical science is never likely to formulate a system that, laying down rules for the guidance of all cases, would leave little or nothing to the judgment of the practitioner.

The address was referred to a committee for publication, and, at its close, a paper was presented upon

THE PATHOGENESIS OF YELLOW FEVER,

by DR. IGNACIO ALVARADO, of Mexico, which was heard with difficulty, on account of the speaker's foreign accent. He accuses a microbe as directly responsible for the disease, and indirectly for its symptoms.

PROF. WALTER B. GEIKE, of Trinity College, Ontario, Canada, then presented a paper upon

THE PREVALENCE AND PECULIARITIES OF PNEUMONIA IN CANADA,

based upon his own experience and that of practitioners with whom he had been in correspondence. In the western part of Canada, pneumonia was more often a secondary than a primary disease, and was especially associated with typhoid fever. Coming eastward, it was not so prevalent, and occurred as an acute primary affection. In the Province of Ontario it occurs frequently, about spring, and is of a more or less asthenic character. In Southern Ontario, malaria has a marked influence upon it, and in the large Ontario cities, it is of a low type. When allowance is made for all other causes, malaria is a more important factor in the production of a low type of pneumonia than any other. In the Province of Quebec, pneumonia is frequent, acute, sthenic, Montreal, for example, thus contrasting with Toronto. Malaria in this region is practically unknown, and, therefore, the type is similar to the pneumonia of the Northwest. In Prince Edward's Island, Nova Scotia, Cape Breton, and Newfoundland, pneumonia is frequent, sometimes almost epidemic, acute, rarely low. In conclusion, the speaker dwelt a moment upon treatment, endorsing Erichsen's views of the treatment of inflammations — that there should be no uniform plan of treating as such, but that one must estimate rather the constitutional power of the patient, than the precise extent of lung involved.

The paper was followed by a discussion upon the cause and treatment of pneumonia, some upholding, and some decrying the pneumococcus as its cause, and at its conclusion the Section adjourned.

TUESDAY, SEPTEMBER 6TH.

The second day's session was opened, in the afternoon, with an audience of about forty, the morning meeting being omitted.

The first paper was by DR. JOSEPH KOROSI, of Buda-Pesth, Hungary, upon

THE PREVENTIVE POWER OF VACCINATION FOR SMALL-POX,

and was based upon some twenty thousand cases of disease seen in Hungarian hospitals. It contained a vast amount of tabulated statistics, incapable of reproduction in an abstract. Among the deductions from these figures was the belief that not only did a larger percentage of the unvaccinated than of the vaccinated die of small-pox, but a larger percentage died from other causes, so that, so far as his observations went, vaccination was unattended with the dangers claimed by its opponents. Vaccination, in his opinion, was preventive of small-pox.

DR. WILLIAM WHITMARSH, of England, then read a paper upon

VACCINATION,

which, he said, had greatly reduced the prevalence of small-pox. In his opinion, however, it did not prevent it, but modified its virulence.

The same gentleman then presented a paper upon

PASTEUR'S TREATMENT,

in which he described in detail Pasteur's treatment of hydrophobia, and exhibited some of his appliances. He then went on to consider the method from a critical standpoint, taking strong ground against its need or efficiency, and asserting that it was not devoid of danger, the ninety deaths which had occurred among the patients proving the latter statement. The fact was that Pasteur was a first-class scientific chemist, but not a physician. We really know little or nothing of the nature of the virus, or of the antidote. The speaker had suggested to the House of Lords a practical test of the Pasteur method, by giving criminals under sentence of death the option of submitting to experiment in this line. Inoculate a man with the Pasteur virus, and then rub into an open wound on his person the saliva of a rabid dog, and you could form an intelligent opinion as to its protective power. In his opinion, the Government encouraged hydrophobia by compelling dogs to be muzzled in warm weather.

These papers were followed by a discussion upon

the value of vaccination to prevent small-pox, after which the Section adjourned.

(To be continued.)

SECTION ON GENERAL SURGERY.

The meetings of the Section on General Surgery are held in the Congregational Church. The first meeting was held on Monday afternoon, September 5th.

The Section was called to order by the President, Dr. Briggs, of Nashville, Tenn., at 3 P. M., who, in a brief address of welcome, opened the Section for work.

The first paper was on

GUN-SHOT WOUNDS OF THE ABDOMEN,

by Charles T. Parkes, M.D., of Chicago.

No subject has interested surgeons more than the treatment of penetrating wounds of the abdomen. In 1885, the whole number of recorded cases of operation for gun-shot wounds of the intestine was but six. Since 1885, thirty-eight cases have been recorded, with eleven recoveries, and, in future, all cases operated upon should be reported, whether successful or not. Surgical interference in appropriate cases is now the generally-accepted view.

The condition and appearances of the external wound give some indication as to the presence or absence of penetration. A single wound of the abdomen affords a hope that the penetration has not taken place, but it is only a hope. Even the presence of a wound of entrance and exit does not positively indicate injury of the viscera. If there is a tract of tenderness continuous from the wound of entrance some distance, it is fair to infer that penetration does not exist. A large bullet-hole indicates penetration. When in doubt, the wound of entrance should be enlarged. In this way, the presence or absence of penetration can be determined, and, with the usual precautions, this does not increase the danger.

In diagnosis, much value cannot be attached to the subjective sensations. The unusually rapid appearance of tympanites in a region ordinarily dull would indicate escape of gas into the abdominal cavity. Localized dulness in the region of the wound, or in the dependent portion of the abdomen, would indicate hæmorrhage. The presence of blood in the urine indicates wound of the kidney, bladder, or ureter. Shock cannot be relied upon, but, when present, the probability of perforation is very great. The rare phenomenon of fæces in the wound is a positive sign of perforation. The presence of persistent nausea and vomiting also points to injury of the viscera. The absence of pulsation in one femoral artery indicates injury of the iliac vessel.

The following cases were reported:

Case I. A man shot himself twice in the abdomen. He was seen four hours after the accident. The wounds were four inches to the left of the median line, the one one-and-one-half inches above the other. One ball had gone entirely through the abdomen, making a posterior opening just under the last rib. From this there was considerable hæmorrhage. There was moderate collapse. Penetration was demonstrated, and then a median incision was made. Five perforations were found, and closed with silk thread. The left kidney was also perforated by the bullet. It was, however, allowed to remain. The patient did well for twenty-four hours, and then failed rapidly from collapse, due to considerable bleeding from the wounded kidney.

Case II. P. I., age forty-five, was shot in the abdomen. He was not seen until sixteen hours after the injury. The wound was in the right iliac region. On opening the peritoneum, fæcal matter escaped. Only one opening was found, and this was closed with the continuous suture. There were evidences of distinct peritonitis, and the man died sixteen hours after operation. The patient would, in all probability, have recovered if the operation had been done earlier.

In the treatment of gun-shot injuries of the abdomen, incision in the median line is the better in the majority of cases. There are exceptional cases, in which enlargement of the original wound answers the purpose. The continuous suture answers every purpose, and as it can be inserted more rapidly than the Lembert, it is preferable. Silk is preferable to catgut in making the sutures. Where resection is required, two methods of procedure may be adopted: In cases where the mesenteric border cannot be saved, section should be made through the healthy bowel, and a triangular portion of the mesentery also removed. The two portions of the bowel are then brought together and secured with sutures, the first suture being introduced at the junction of the mesentery and intestine. In no case had the author found it necessary to use more than one row of sutures. All raw surfaces should be covered with peritoneum. The second method is applicable in cases where the mesenteric border is not injured. In these cases, the section does not involve the mesenteric border of the intestine. The injured portion is alone removed, and the edges of the healthy bowel brought together with the continuous suture. Where the omentum is injured, the hæmorrhage is often severe, requiring the removal of a large portion of the structure. All slits and lacerations in the omentum should be closed by continued sutures. In perforation of the stomach, there is no difficulty in closing the wound after it is found. Where there is no complication, wounds of the stomach usually heal satisfactorily. In gun-shot wounds of the liver, the surface should be brought together by deep sutures. The same procedure may be employed in the case of the spleen, but where this organ is badly lacerated, extirpation is indicated. Perforating wounds of the kidney call for extirpation. Perforation of the liver, spleen, or kidneys, with a similar injury of the small intestines, greatly increases the gravity of the case, and such cases will usually end fatally. Wounds of the bladder call for suture.

Special stress was laid on the necessity of seeking out all wounded bloodvessels, thus preventing the danger of primary or secondary hæmorrhage. There should be a careful search made for all wounds of the intestine, the bowel being examined in a systematic manner. Tight sutures should be avoided, for these will lead to sloughing and extravasation. If the peritoneal surfaces are laid in contact and kept there for a few hours, adhesions will take place.

AN EXPERIMENTAL CONTRIBUTION TO INTESTINAL SURGERY, WITH ESPECIAL REFERENCE TO THE TREATMENT OF INTESTINAL OBSTRUCTION,

by N. Senn, M.D., of Milwaukee, Wis.

The indications in the treatment of intestinal obstruction are to remove or render harmless the cause

of the obstruction, and the immediate restoration of the continuity of the intestinal canal. Where the cause cannot be removed, it is to be rendered harmless by forming an anastomosis between the portion of bowel below and that above. One hundred and fifty operations were performed on animals. The principal forms of intestinal obstruction were produced artificially, and the attempt was made to devise some new operation, whereby the obstruction may be relieved where the removal of the cause is not possible. The length of time required in the performance of most of the present operations is their great contraindication. By simplifying the method of operation, the author had been able to lessen the time required. To prevent extravasation during the progress of the operation, the author had employed a narrow rubber band, tied round the intestine with sufficient force to occlude it. He had never observed any injurious effects following the use of elastic compression.

The study was first directed to simple stenosis, which was produced by cutting out a semilunar portion of the bowel. Traumatic stenosis from this cause becomes a source of danger from obstruction or from perforation, when the lumen of the bowel is reduced more than one-half. Where excision of the bowel is required for injury, not more than one-half should be taken away. If more is required, circular excision should be resorted to. Longitudinal suturing of wounds on the mesenteric side of the intestine should never be practised, for this is invariably followed by gangrene and perforation, through interference with the blood supply of the portion of bowel corresponding to the vascular defect. In circular constriction of the bowel, the immediate cause of gangrene is obstruction to the venous supply of the bowel and takes place first at the point most remote from the cause of obstruction.

Flexion was then produced by removing a portion of the bowel transversely, and suturing of the wound. It was found that on the convex side, a defect one inch in width could be closed by transverse suturing without causing obstruction by flexion. In such cases the flexion is subsequently corrected by a compensating bulging of the mesenteric side of bowel. Closing of such a wound by transverse suture on the mesenteric side of the bowels, may give rise to intestinal obstruction by flexion, and to gangrene and perforation by seriously impairing the blood supply of the portion of bowel involved. Flexion caused by inflammatory and other extrinsic causes, gives rise to intestinal obstruction only when the functional capacity of the flexed portion of the bowel has been diminished or suspended by the causes which have produced the flexion, or by subsequent causes independent of the flexion.

Volvolus is simply another form of flexion. Volvolus gives rise to symptoms of obstruction, when the causes which have caused the rotation of the bowel, have at the same time produced impairment or suspension of the peristalsis in the portion of bowel which constitutes the volvolus, or when a diminution or suspension of peristalsis follows in consequence of the rotation.

In invagination, one of the most important factors in preventing disinvagination and in inducing gangrene of the intussuscipiens is the accumulation of intestinal contents above the seat of invagination. Spontaneous reduction is not more frequent in ascending than in descending invagination. The immediate cause of gangrene is obstruction to the return of venous blood by constriction at the neck of the intussuscipiens. Ileo-careal invagination, when recent, can frequently be reduced by distentions of the colon and rectum with water, but this method of reduction must be practised with great care and gentleness as over-distention of the colon and rectum is productive of multiple longitudinal lacerations of the peritoneal coat, an accident which is followed by the gravest consequences. The competency of ileo-careal valve can only be overcome by over-distention of the coreum, and is effected by a mechanical separation of the margins of the valve, consequently it is imprudent to attempt treatment of intestinal obstruction beyond the ileo-careal valve by injections per rectum.

In a study of the effects of enterectomy, it was found that in dogs, resection of more than six feet of the small intestines was uniformly fatal, the cause usually being the immediate effects of the trauma. Resection of more than four feet is incompatible with normal digestion, absorption, and nutrition, and often results in death from marasmus. In case of extensive intestinal resection, the remaining portion of the intestinal tract undergoes compensatory hypertrophy.

It was also found that physiological exclusion of an extensive portion of the intestinal tract, does not impair digestion, absorption, and nutrition as seriously as the removal of a similar portion by resection. Fæcal accumulation does not take place in the excluded portion of the intestinal canal.

Objections was made to the various forms of suture used in circular enterorrhaphy for three reasons: first, the time required for their insertion; second, the danger of puncturing the bowel; and third, the interference with nutrition which they cause. The author recommends the use of catgut in preference to silk. It was recommended that a rubber tube be introduced into the bowels and the wound closed over it by two sutures. Ectropia is prevented during operation by compression.

The line of suturing or neck of the intussuscipiens would be covered by a flap or graft of the omentum, in all cases of circular resection, as this procedure furnishes an additional safeguard against perforation. In circular enterorrhaphy continuity of the peritoneal surface should be secured where the mesentery is detached by uniting the peritoneum with fine catgut before the bowel is united. This furnishes better security against perforation on the mesenteric side. A strip of the omentum two inches wide is placed around the line of junction and secured with the sutures.

The formation of a fistulous communication between the bowel above and below the seat of obstruction should take the place of resection and circular interorrhaphy in all cases where it is impossible or impracticable to remove the cause of obstruction, or where the pathological conditions which have given rise to the obstruction do not constitute an intrinsic source of danger. In performing this operation the speaker, after experimenting with plates of various materials adopted decalcified, or partially decalcified bone. This procedure is indicated as a substitute for gastro-enterostomy. The stomach is exposed and a longitudinal incision is made in its anterior aspect, so that a decalcified bone plate, having a sufficiently large opening, may be introduced. This is secured in proper position by sutures introduced in the margin of the fistulous wound. The upper portion of the small intestine is treated in the same way, and the two parts are thus

brought in apposition and secured with silk sutures. In almost every instance where this had been done the result had been favorable. While the ordinary operation requires at least an hour for its performance, this operation can be performed in the space of ten minutes. The same method of treatment is applicable throughout the intestinal canal, where it is desired to form a fistulous communication between the bowel above and that below. If there are indications of sloughing of the bowel, or threatened gangrene, no such procedure should be adopted. An ileo-colostomy, or an ileo-rectostomy can also be done by lateral implantation, the small intestine being introduced into an opening made in the large intestine and secured with a few stitches. In this case, a piece of rubber tubing is inserted into the bowel to keep it patulous. The restoration of the continuity of the intestinal canal by perforated approximation plates or lateral implantation should be done in all cases where circular enterorrhaphy is impossible on account of the difference in size of the lumina of the two ends of the bowel. In cases of multiple gun-shot wounds of the intestine involving the lateral or convex side of the bowel the formation of intestinal anastomosis by uniting two of the openings with decalcified bone plates, should be preferred to the use of sutures as this procedure is equally, if not more safe, and requires less time.

The author had also made certain experiments with reference to the time required for the formation of adhesions. Definitive healing of an intestinal wound is only completed after the formation of a net-work of new vessels in the product of tissue proliferation from the approximated serous surfaces. Under favorable circumstances quite firm adhesions are formed between the peritoneal surface within six to twelve hours, which effectually resist the pressure from within outwards. Scarification of the peritoneum at the seat of approximation hastens the formation of adhesions and the definitive healing of intestinal wounds.

Omental grafts from one to two inches in width and sufficiently long to encircle the bowel, retain their vitality, become firmly adherent in from twelve to eighteen hours, and are freely supplied with bloodvessels in from twenty-four to forty-eight hours. Omental transplantation or omental grafting should be done in every circular resection or suturing of a large intestinal wound, as this procedure favors the healing of the visceral wound and furnishes an additional protection against perforation.

The Section then adjourned.

(To be continued.)

— "Take my advice, and when you get a prescription put up at a drug store never ask how much it is," said one gentleman to another the other day. "Why not?" he was asked. "Because the clerk will 'size you up,' as the boys say, guess how much money you have got, and charge you your pile." — "What do you advise?" — "Just this. When the urbane compounder of medicines hands forth your prescription, just look wise and lay down a quarter. Now the chances are that the drugs in the preparation don't cost over a dime. He will look at the quarter, study a minute, and then make up his mind that he has been foolish enough to sell you the same dose for twenty-five cents at some past time, and he'll take it and not say a word. Lay down a dollar, however, and it will be just the same — no change. Try it and see."

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 8, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

Subscription Terms: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 Boylston Street, Boston, Mass.

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

Our readers will find in the present enlarged issue of the Journal, specially prepared reports of the proceedings in the General Sessions of the Ninth International Medical Congress, now in progress at Washington for the first three days, Monday, Tuesday and Wednesday; of the Section of General Medicine for the first two days, Monday and Tuesday; and of the Section of General Surgery for the first day, Monday.

A special correspondent also offers a bird's-eye view of the social and other less strictly professional features of the Congress. These reports and the correspondence will be continued in the next issue; by which time, when the smoke and dust of the conflict have somewhat cleared away, and those of the contestants who survive have departed to listen to the roar of Niagara, a better view can be obtained of the situation and a fairer estimate formed of the net results.

From the latest reports received up to the moment of writing it would seem as if, in point of numbers registered, the Congress had been a success. The number of foreigners present was comparatively small and was said on Thursday to be about 150. The entertainments were carefully provided for and amply appreciated.

The work of the Congress has varied in interest and vigor in the different Sections and in most of them increased in activity somewhat in successive days. The Sections on General Surgery and Obstetrics have presented ample material and excited lively and fructifying discussions.

The medical work of the General Sessions and that of the Section of General Medicine, had up to the date of writing, disappointed expectations, and been scarcely up to what should be demanded of the occasion.

The heart-burnings seem to have exhausted themselves in anticipation, and, with trifling exceptions, an edifying harmony has prevailed.

MEDICAL NOTES.

NEW YORK.

— The Governors of the New York Hospital Society have, it is said, decided upon the removal of the insane department of the institution, the well-known Bloomingdale Asylum, to a more remote position, and it is probable that the vicinity of White Plains, West Chester County, where the Society already owns a farm of some three hundred acres, will be selected. The land and buildings of the Bloomingdale Asylum are valued at from four to five millions, and the entire property of the hospital society is rated as fifteen millions.

— There is now in course of erection at Elmira, an admirably constructed and fully equipped hospital, which is to be known as the Arnot-Ogden Memorial Hospital, and is the free gift of Mrs. William B. Ogden, of New York, to the city of Elmira.

Correspondence.

[From our Special Correspondent.]

LETTER FROM WASHINGTON.

NOTES AND GOSSIP ABOUT THE INTERNATIONAL MEDICAL CONGRESS.

WASHINGTON, Wednesday Evening, Sept. 7, 1887.

MR. EDITOR,— Washington, at this season usually quiet and deserted, this year fairly swarms with doctors, wearing upon their coats the big medal and blue ribbon, the badges of their membership of the International Congress. Walkmen, bellboys, and hotel clerks have grasped the situation, and you hear nothing but "Doctor," "doctor," reminding you of a lot of first-year medical students. The weather is simply charming, albeit a trifle warm, but there is a gentle breeze and the nights are reasonably cool. The local arrangements for the Congress seem to have been well made, the general meetings being held in a handsome and commodious Opera House, conveniently near the hotels. The Sections meet in halls, churches, etc., as near the Opera House as could be expected, usually quite large enough for the numbers the Sections collect, and equipped with the necessary appurtenances. The social interests of the Congress suffer from the fact that Washington in September, is, as Dr. Garnett, of the Committee of Arrangements, put it, practically deserted by a large part of its citizens, but a certain amount of entertainment in this line is provided. The foreign guests are looked after by an excursion to Mount Vernon on Saturday, and on their return they are to be taken to Niagara Falls. These trips can also be taken by American members, if they pay for them, at reduced rates. Besides a reception at the White House and a lunch at the Pension Building, the members of the Congress are invited by Secretary Whitney, of the Navy Department, to a reception at his country residence; there will be several private receptions; the Treasury Building is open for the occasion daily, and various public institutions, like the Government Asylum for the Insane have sent invitations to the Congress.

The first of the social exercises of the occasion was held Monday evening in the shape of a *conversazione* at the United States Pension Hall, which was elaborately decorated for the occasion. There was a very large attendance, but no special ceremonies — a sort of huge promenade concert, of whose opportunities the Washington people very largely availed themselves.

The total registration of members of the Congress up to Wednesday was a little rising 2,500, including about 110 foreigners. As the registration is carried on by letter as well as personally, this is not an exact representation of the actual attendance. Making due allowance for this fact, it is probable that the real attendance is something over 2,000. There are some noteworthy facts in this regard. There are very few New England physicians, a very small representation from New York, and only a part of the Philadelphia men. Some of the Canadian representatives, naturally more familiar with Eastern men, lament the absence of many whom they expected, and were especially desirous to see.

The foreign delegation includes not many men of note. Among the best known are: Dr. Leon Le Fort, of Paris, Surgeon at the Hôpital Necker; Prof. Unna, of Hamburg, Germany, Editor of the *Journal of Dermatology*; Dr. Joseph Korosi, of Buda-Pesth, Hungary, Director of the Hungarian Bureau of Medical Statistics; Dr. T. Grailly Hewitt, of London, the well-known gynæcologist; Dr Mariano Semmola, of Naples, Italy, a Senator in the Italian Parliament; Dr. Apostoli, of Paris; Grant Bey, of Cairo, Egypt; Dr. A. Martin, of Berlin.

Among the few Eastern men of note are Dr. John Homans, of Boston, who came on Monday to read his paper on his results in laparotomy before the Surgical Section, and went back the next day; Dr. Gordon, of the Maine General Hospital of Portland, who was an interested participant in the proceedings of the same Section; and Dr. M. H. Richardson, of Boston, who came Tuesday to read his case of successful gastrotomy.

It will be remarked that among the exercises of the first day was the election of an enormous list of vice-presidents, prepared for the occasion, most of whom were probably at home. A delegate made a courageous attempt to interrupt the cut-and-dried programme and to confine the officers to those in actual attendance, but he was promptly and effectually sat upon by the President.

The exhibition of drugs and medical appliances which has become a part of every medical gathering, is in full blast at the Opera House, and the "sample fiend" is omnipresent. Some of the members will need a trunk to carry off their plunder and will be "stocked up" for a year. It is due to the exhibitors, however, which include about all the large drug houses and instrument makers of the country, to say that their wares made a very large and a very handsome exhibit, at least before the Philistines despoiled them.

Probably not the least enjoyable event to a large majority of the members of the Congress was the reception at the White House on Tuesday evening, by the President and Mrs. Cleveland. The guests were received in the Blue Room, and were announced by Surgeon-General Hamilton to Col. Wilson, who made the introductions. At eight o'clock, when the reception began, there was a line reaching from the door and through the grounds on to the Avenue, and the hour of closing, which had been fixed at nine, was nearer eleven. There were a lot of people who had no connection with the Congress, but who availed themselves of the chance to shake hands with the President and his wife. The Marine Band played, the East Room was very handsomely decorated with flowers and potted plants, and the whole lower part of the house was thrown open. It partook, of course, of the character of large receptions in general, but was on the whole, a very pleasant occasion, marred only by the intrusion of outsiders in overwhelming numbers. After the reception, many of the members went over to the Corcoran Art Gallery, which had been opened for them.

Among the humors of the occasion is a story to the effect that a prominent medical chemist across the sea wrote to the committee of arrangements some time ago that he supposed America would want to come up to England in style, and that as music formed so marked a feature of the London entertainment, it had occurred to him to come over and bring his musical daughter for the moderate sum of a hundred guineas. It is needless to say that the fair *cantatrice* is not here, nor the eminent chemist.

The disadvantages attending the assemblage of a large body of men in a Democratic city, without proper arrange-

ments, have been markedly illustrated. In the first place, it is stated in the Washington papers that there were between four and five thousand people at the gathering at the Pension Hall on Monday evening. As the total registration at that time did not exceed two thousand, it may easily be computed how large was the proportion of outsiders. The next night, at the President's reception, the same spectacle was seen of non-members of the Congress thrusting themselves into a place not designed for them. This was carried to such an extent that many of the foreign guests came and went without seeing the President, unable to obtain entrance without long waiting. The upshot has been, that it was announced at the session of Wednesday that it was feared that tickets to the banquet of Thursday had been improperly obtained; and it was therefore decided to cancel them and issue new ones.

There was an unfortunate incident which marred a little the exercises of Monday. It seems that Dr. Francesco Durante, of Italy, the Governmental representative to the Congress, had been asked to reply to the speech of welcome by Secretary Bayard. When, later, he made some inquiries about the length of his speech, he discovered that he had been set aside to make room for Dr. Semmola. Dr. Hamilton, the general secretary of the Congress, is represented in the papers as saying that Dr. Semmola claimed, that, as an Italian senator, he was the proper person to speak for Italy, and, that, if his claim was not conceded, he would withdraw. As the Committee were already short of papers, they yielded to Semmola, and Dr. Durante therefore wrote a sharp letter, withdrawing from the Congress. The affair was smoothed over, however, as Durante presided over the Congress on Wednesday, while his confrère, Semmola, read his paper.

Another tempest in a tea-pot arose from the fact that Dr. Murphy, of Dublin, fancied he was slighted by not being invited to a banquet to the foreign medical editors, Monday evening. He also wrote a letter of withdrawal, but the committee explained to him that the banquet was a private affair, not officially connected with the Congress.

There is a wide difference in the programmes and interest of the various Sections, and the attendance upon them. For instance, the Section devoted to military surgery runs over with papers and has a definite programme, which is carried out so far as time will allow. The Sections on general surgery, gynæcology, diseases of children, and others, perhaps, are well attended, and evoke spirited discussions. The section on general medicine is pretty much a failure. There is no regular programme, the promised papers are few, and those that materialize are fewer yet. The morning sessions of this Section have been given up, for lack of papers and attendance. This may partly be attributed, perhaps, to an essential lack of interest in the subject itself. As a Canadian physician put it, "We are all now surgeons or specialists, we stick to the rectum or what not,— we are no longer doctors."

The programme of the general sessions has been much changed, also, on account of the lack of material for their continuance. Dr. Luteaud, of Paris, and Dr. Neudörfer, of Vienna, who were booked for addresses, on "The Influence of American surgeons on Gynæcology in Europe," and on "Military Surgery," respectively, failed to come to time. So that instead of two addresses daily before the general session, there was but one.

Berlin will probably be chosen for the place of meeting of the next Congress.

(To be continued.)

REPORTED MORTALITY FOR THE WEEK ENDING AUGUST 27, 1887.

Deaths reported 2,281: under five years of age 1,035; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 731, consumption 257, lung diseases 112, diphtheria and croup 89, typhoid fever 79, malarial fever 32, whooping-cough 27, scarlet fever 11, cerebro-spinal meningitis nine, puerperal fever seven, measles three, erysipelas two. From malarial fever, New York 10, Brooklyn seven, Philadelphia and Baltimore five each, New Orleans four, Nashville one. From whooping-cough, Philadelphia six, Boston and Baltimore five each, New Orleans, District of Columbia, Milwaukee, Nashville and Fall River one each. From scarlet fever, New York four, Brooklyn three, Boston two, Pittsburgh and Fall River one each. From cerebro-spinal meningitis, Worcester three, New York, Pittsburgh, Milwaukee, Lowell, Somerville and Taunton one each. From puerperal fever, Pittsburgh three, Brooklyn two, New York, District of Columbia and Fall River one each. From measles, Boston two, Philadelphia one. From erysipelas, New York and Brooklyn one each.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending August 13th, the death-rate was 23 7. Deaths reported 4,191: infants under one year of age 1,764; acute diseases of the respiratory organs (London) 175; diarrhœa 943, whooping-cough 104, measles 78, scarlet fever 57, fever 39, diphtheria 29.

The death-rates ranged from 13.2 in Halifax to 31.4 in Manchester; Birmingham 24.8; Hull 26.2; Leeds 21.0; Leicester 25.1; Liverpool 24.9; Manchester 31.4; London 23.3; Newcastle-on-Tyne 30.2; Nottingham 21.9; Sheffield 24.6.

In Edinburgh 19.6; Glasgow 18.5; Dublin 31.5.

The meteorological record for the week ending August 27, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM AUGUST 27, 1887, TO SEPTEMBER 2, 1887

SMITH, JOSEPH R., lieutenant colonel and surgeon. Ordered to report in person to the surgeon general of the army, on September 2, 1887, on business connected with the public service, and on completion thereof to return to his proper station. Par. 9, S. O. 198, A. G. O., August 26, 1887.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING SEPTEMBER 3, 1887.

DEAN, RICHARD B., medical director. Detached from duty as member of Examining and Retiring Boards and to Hospital, Chelsea, Mass.

PECK, GEORGE, medical director. Ordered as delegate to International Medical Congress revoked.

SIMONS, M. H., surgeon. Detached from "Constellation" and to the Naval Academy.

ROGERS, B. F., surgeon. Detached from Marine Rendezvous, New York, and to the "Alliance."

FIELD, JAMES G., assistant surgeon. Detached from the "Vermont" and to Marine Rendezvous, New York.

HENRY, C. P., assistant surgeon. Ordered to the "Ossipee."

LUMSDEN, G. P., passed assistant surgeon. To the "Boston."

ATLEE, LOUIS W., assistant surgeon. Restored to duty.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING AUGUST 27, 1887.

BAILHACHE, P. H., surgeon. Granted leave of absence for thirty days. August 26, 1887.

CARTER, H. R., passed assistant surgeon. Granted leave of absence for twenty-seven days, August 25, 1887.

YEMANS, H. W., passed assistant surgeon. Resignation accepted to take effect September 30, 1887, and leave of absence extended to that date, August 24, 1887.

NORMAN, SEATON. Granted leave of absence for six days, on account of sickness, August 27, 1887.

SOCIETY NOTICE.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next meeting of the Society will be held at No. 19 Boylston Place, on Thursday, September 15th, at 4 o'clock, P.M. Paper: "Uterine Fibroma with Pelvic Cellulitis," by Dr. Mary E. Bates, of Newton Centre.

H. J. HARRIMAN, M.D., *Secretary*.

DEATH.

Died in Winchendon, Mass., September 3, 1887, Charles Eliot Ware, M.D., M.M.S.S., of Boston, aged seventy-three years.

OBSERVATIONS ON THE PUERPERAL PELVIC LIGAMENTS.[1]

BY STEPHEN W. DRIVER, M.D., OF CAMBRIDGE.

Is there a constant and normal relaxation of these during pregnancy and at term?

Does it occur in the non-puerperal woman?

Does it continue after recovery from confinement? More or less during the early and middle life of a woman?

What are the factors that *prevent*, *determine* or *vary* this relaxation? Does this relaxation facilitate delivery?

In the following observations the beginning of an answer to these and other questions will be attempted.

PREFATORY REMARKS.

Dr. Thomas Denman, who saw his first case of relaxation of the symphysis pubis in 1774, remarks, "It was for many centuries a received opinion that these cones, though joined together in such a manner as scarcely to afford any suspicion of a separation, were always separated at the time of parturition, or that there was a disposition to separate. But this opinion has been controverted by many writers. But notwithstanding all that has been said, I know *not* that we are authorized to say that a separation or a disposition to separate prevails universally at the latter part of pregnancy or during parturition. Yet that these effects are often, if not generally produced, may be inferred from the pain and weakness so often mentioned and complained of at the parts where the bones of the pelvis are joined together. We leave the question to be settled by future observations."

Dr. Denman seems to have seen very interesting cases, to have taken a very correct view of the subject, and yet with all his shrewdness he did not hit upon a method of actually testing the separation or mobility of the pelvic bones, but only inferred it from symptoms. On page 76 he says, "The opinion of the separation was chiefly founded on the particular attitudes and positions in which the patient sought relief."

Baudelocque says, page 23, "Such has been in all ages the variety of opinions on this point. It is very certain that the bones of the pelvis *may* separate in labor, but that it does not happen so often as has been thought; and experience demonstrates that far from being common it is very rarely met with."

Finally, "According to these observations, the separation of the bones of the pelvis will appear to be an unnecessary accident."

Dewees says, page 22, "We may adduce the following reasons as conclusive against this relaxation being a natural provision:

"1. It is certain that in cases of autopsy the symphyses were very rarely found to have yielded in the *slightest* degree.

"2. That it is not more frequent in the distorted than in the normal pelves.

"3. Were it an arrangement of nature, the means do not seem adequate to the end; that is, relaxation does not enlarge the diameters.

"4. That where it has been found to have taken place even in a slight degree, it has never failed to create either temporary or permanent inconvenience."

Churchill says, page 40, "From a fair observation of the cases on record, we may conclude that it never takes place as a natural process, but that we occasionally meet with it as an accident."

Playfair, "The ligaments and cartilage become swollen and softened, and the synovial membranes are augmented and distended with fluid."

McClintock, in a note to his edition of Smellie, says, "The slightest physiological degree of separation could not be detected in the living subject by any ordinary modes of examination; and where the separation has been considerable and consequently easy of recognition, very unpleasant consequences with marked symptoms have been present."

Both statements are untrue, for I shall show that a very ordinary "mode of examination" will detect the slightest degree of motion, and in a great many cases a considerable separation, easily recognized, may have no "unpleasant consequences."

MY PREFATORY CONCLUSIONS.

It never seems to have occurred to any of the old or new observers (save one New York man, I believe) to make a test of the actual condition of the pelvic symphyses in child-bed through a long series, say of 1,000 cases; to test these same cases six months after delivery, and also to test all cases of virgins and women before any childbirth.

In the following pages I shall try to give the results of actual tests through a series of nearly three hundred cases occurring in my own practice. It would have been a great aid to deciding this long doubtful question, if, in addition to their admirable series of minute observations, the physicians of the Boston Lying-in Hospital had made this test through their first 1,000 cases.

The ligaments concerned in the following observations are,

1st. The pubic (a); the superior pubic (b); the sub-pubic (c); the anterior pubic and the posterior pubic.

2d. The sacro-iliac (s); the anterior sacro-iliac ligament, a continuous band (b); the posterior sacro-iliac ligaments, a group of four bands.

There also comes into consideration the junction cartilage or inter-packing of the sacro-iliac and pubic joining. "Occupying two-thirds of the length and the posterior third of the centre of the junction of pubes we find a true arthrodial articulation, six lines in length, two in breadth, shaped like an almond, lined by a synovial membrane containing a small quantity of synovial fluid."— *Churchill.*

In testing almost three hundred cases at the puerperal period, I think I have determined the fact that the ligaments of the pubic junction vary very much in their development; in many cases the sub-pubic and anterior especially seem to be a strong, firm and well-developed band making a smooth arch; in others a careful examination would almost lead one to believe that there was no true sub pubic or anterior ligament, but that the joint depended upon the cartilage or membrane to hold it together. This is often the case in delicate women; you can feel the bony structure almost as plainly as in the pelvis I hold here. That a similar proportional development prevails or exists in the sacro-iliac ligaments may be inferred from a study of the skeletons and from certain facts that I have observed. They cannot be tested because they

[1] Read before the Massachusetts Medical Society, June 7, 1887, and recommended for publication by the Society.

(the sacro-iliac) are so deeply covered in the overlying tissues. If at the time of confinement these ligaments are relaxed, and if also the interstitial cartilage is deficient or in a soft and undeveloped stage, or infiltrated, then the pubic bones, instead of forming a firm arch, move the one on the other, as the patient turns on the bed, draws up her limbs, or later attempts to stand or walk. This motion is, at the pubes, up and down, and in extreme cases of relaxation, backward and forward. At the sacro-iliac it is pivotal, the sacrum being the fixed point on which the iliac turns.

(Here the reader demonstrated how sometimes the sacrum is the pivot, and sometimes the iliac is the fixed point.)

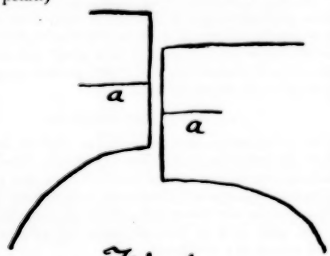

Fig 1

Both sacro-iliac junctions may be relaxed, or only one. In testing the cases following, I have been accustomed to use this method, either immediately after confinement, or within the first three days. While the patient is lying flat on her back, with both legs extended, I pass my forefinger within the vulva, under the arch, pressing back with the end of the finger the meatus urinarius, and thus having the pubic junction resting on the first joint or phalanx, I ask the patient to draw up her leg, first one, and then the other. I can perceive the slightest motion, for there is nothing between the ligaments and my finger but the mucous membrane. The weight of the leg is a strong lever-age, acting through the iliacus and psoas muscles as they pass over the horizontal ramus of the pubes. The internal muscles of the thigh that are attached to the pubes also aid. For instance, as the patient draws up the left leg, the left pubic ramus will be pressed downward, and its motion will be felt, and can be measured by the finger. If the right leg be lifted from the bed, the right pubic ramus will be depressed. When the test is made with the patient standing on her feet, the reverse will be the case; if she stands on her left foot, the weight of the *right* leg and side of the body will carry that side down, and the left pubic ramus will go up; if she stands on her right foot, the right ramus will ascend. This is the most radical test of pubic motion. If the tissues of the mons veneris are thin, the motion can well be perceived with the fingers pressed on the front of the junction, or even grasping it above and below.

The amount of motion that you can determine at the arch is not the measure of the whole motion at the joint; that is, if the pubic bone of the left side, for instance, projects by the other one-fourth of an inch, one-fourth of an inch does not express the whole motion. See the position of this in Figure 1, where *a* indicates the vertical centre of the pubic junction, with the patient standing on her right leg, and the left bone projecting one-quarter of an inch.

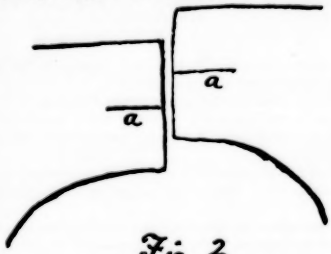

Fig 2

Now let the patient stand on her left leg, and the parts will assume the position of Figure 2, where the right bone projects one-quarter of an inch.

But, however, the vertical centre has not moved back merely to its normal, a distance of one-fourth of an inch, but by that normal, one-fourth of an inch upward, making the whole motion one-half of an inch, or double the measure of projection under the arch.

OBSERVATIONS, FIRST SERIES, 200.

Since January 1, 1878, I have made it a rule to test every case of confinement, if possible, and have recorded the results under the following heads. The series includes 224 cases:

Series (Not tested, 24; Tested, 200)			224
No motion	52	or 26	per cent.
Slight "	62	or 31	"
Marked "	34	of 17	"
1-16 of an inch motion	8	or 4	"
1-8 " "	16	or 8	"
1-4 " "	22	or 11	"
1-2 " "	6	or 3	"
	200		

Requiring treatment, 4, or 2 per cent. Of these, 2 Americans, delicate; 2 Irish-Americans, 1 hardy, 1 delicate; ages from 24 to 32; motion in 3 cases, one-half of an inch, in 1, only one-eighth of an inch.

THIRD HUNDRED CASES.
SECOND SERIES, 300; 25 NOT TESTED.

Firm	16	plus 52	equals 68,	24	2-3	per cent.
Slight motion	25	" 62	" 87,	32		"
Marked "	6	" 34	" 40,	15		"
1-16 of an inch motion	4	" 8	" 12,	4	1-3	"
1-8 " "	15	" 16	" 31,	11		"
1-4 " "	8	" 22	" 30,	11		"
1-2 " "	1	" 6	" 7,	2	1-2	"

Requiring treatment, 4, or 1½ per cent. No motion in 25 per cent. Bones movable in 75 out of 100. Decided mobility, 120 out of 275, or 44 per cent.

Dewees and Baudelocque say that it is rare to find a slight degree of separation.

FIRST SERIES OF 175 DIFFERENT INDIVIDUALS.

American	56	English	14
Irish American	47	Scotch	4
Nova Scotian	6	French	3
Colored	1	Swedish	1
Irish	42	Italian	1

One-half inch motion,	6,	3 3-7	per cent.
One-fourth inch motion,	16,	9 1-7	"
One-eighth inch motion,	27,	14 2-7	"
One-sixteenth inch motion,	7,	4	"
Marked motion,	26,	14 6-7	"
Slight motion,	42,	24	"
No motion,	51,	29 1-7	"

Pelvis was found firm in 51 out of 175, or 29 per cent.; 70 per cent. movable.

Mrs. G., aged twenty-six, American, of abundant means; third confinement. Seen by me but once before confinement. During the last month was unable to walk well; shuffled in her gait; was unusually large. Taken in labor, November 11, 1873. Found her with os dilated and bed flooded with liquor amnii; yet I ruptured a second membrane and there was a further gush of water. Labor short and easy. On the fifteenth day patient said to me, "What makes my bones crack and snap every time I turn in bed?" "Bones crack! what do you mean? what bones?" I looked incredulous, as doctors do look when they think their patients are talking bosh. "Why, these bones right here," said she, putting her hand on her symphysis pubis. I, of course, put my hand on the junction and made her turn over, first one side and then the other, asked her to draw up first the right leg and then the left. The displacement was excessive, one ramus slipping by the other with an audible snap like the muffled slipping of a dislocated joint into its socket. I was very much astonished, as I had read of such a case but considered its occurrence a most rare and remote possibility. I made the test, as I have before indicated, with my finger under the arch, and it was apparent that the motion was a full half inch. There was great tenderness over the symphysis. I proceeded to treat this case with a strong band of twilled cotton, five inches wide, fastened as firmly about the hips as the patient could bear; this was kept from slipping upwards by two perineal straps one inch wide, stuffed with hair to prevent chafing. This case was so extreme that my patient did not attempt to walk till the fiftieth day. Even then she was inclined to slide her feet along the floor. Inasmuch as she had been unable to go up and down stairs before her confinement, I had an elevator constructed, and she never walked over the stairs for a year. In May, 1874, she became pregnant again, and there was still a considerable mobility, I had a band constructed to support the abdominal tumor, which was applied after the uterus arose from the pelvis. She was confined in March, 1875, with no untoward symptoms, and there was but little more separation than during the pregnancy. I used the band as a precaution, and she got up with no impairment of her walking powers. In June, 1879, the motion of the bones at the pubes was very marked, and yet no complaint was made by the patient. Also I tested the case at the beginning of 1880, and found no perceptible change, in six years and six months.

I think that the large uterine tumor before the confinement in 1873 acted on the pelvic bones like a great elastic dilating cone, and so tended to spread the bones. In this case there were tenderness and lameness in the *left* sacroiliac synchondrosis, before her confinement. I think this indicated motion only in L. S. I. junction.

Mrs. M., twenty-four years old, very delicate and anæmic before marriage; American; confined February 22, 1875, at seven months; has had several miscarriages; had concealed uterine hæmorrhage in the first stage of labor; large flat clots were expelled with the child. Did well. On the twenty-first day after confinement tried to walk. I asked her to try in my presence; she crept or rather shambled across the floor, complaining bitterly of pain at the symphysis pubis. I tested her by putting my forefinger under the arch and making her stand first on one leg and then on the other, and also making her walk. A limited amount of mobility was found, less than one-eighth of an inch, but very marked, and also great tenderness of the junction.

I put on a firm five-inch twilled cotton band with perineal straps, and she was immediately able to walk with comfort; all complaint ceased after one month. I examined the patient on December 31, 1878, three years after, and found the symphysis still movable. I made the test as I have indicated, making the patient walk while I held the forefinger under the arch. Although the motion was evident, she felt not the slightest inconvenience. I have seen cases where after confinement the amount of motion was much greater, say one-half an inch, and yet there was no pain or impairment of walking power. This case seems to show that the pathological condition is of more importance than the amount of mobility.

December 11, 1878. Mrs. B., confined, fourth child, short labor, second stage one hour. Seen on the fourth day; said she felt well; said it hurt her to move her left leg; left leg was helpless; said "I was the very same way after first child; could not get around for four or five months; seemed as though it twisted that bone down in front when I tried to walk." I examined the S. P. and found marked relaxation, one-half inch motion, strong. Seen by Dr. Nichols and myself December 16th. He found the same relaxation marked; it was a curiosity to him, as it was the first case he had ever examined. Patient gave the following history of her first confinement, which happened two days before the Boston fire. Within a month found her bones hurt her when she moved in bed. Tried to get up at usual time, could not walk, seemed as if that bone right down in front was being twisted like a soft veal bone; she illustrated with her hands. Was obliged to stoop when she walked, with her hands on her knees; used a chair in getting about the room, and had to lie down a good part of the day. Went out of doors for the first time in March. Dr. Q., of Taunton, attended her; did not examine her, did not put on band, did not treat her in any way after confinement. Patient got well without special treatment, and did hard work. I attended her in second and third confinement; she did well in both. A short time after second, complained of pain in left hip, which disappeared quickly under simple treatment. No trouble whatever after the third. She has always worked very hard since I have known her.

I applied a five-inch bandage about the hips, with directions to keep it as tight as she could bear, and to remain in bed. Seen again December 26th; she was up and about; excused herself on the ground that her child was taken sick; limped a little when she walked; said that the bandage helped her very much, but that the stays going between the thighs hurt her. I examined and found the bandage high up off the hips

and about the waist. I suppose it helped her all the same, for in my subsequent visits I sometimes found it off and sometimes on, and yet she continued to improve. This time I tested her with forefinger beneath the pubic arch as she walked across the floor. S. P. tender; when she threw her weight on the left foot the right ramus descended, on right foot left ramus went down, the whole displacement at least half an inch. She felt pain only in the left sacro-iliac synchondrosis; no motion in right sacro-iliac synchondrosis; gait shuffling. I forbade her to go over the stairs, told her to keep the bandage tight, and explained to her her condition completely. In less than a month she was doing her work as usual and carrying heavy loads of coal upstairs. I examined her at the end of a year and found plenty of motion, yet she was doing hard work and called herself well. I examined her last time, December 20, 1880, and still found plenty of motion.

The fourth case was not seen by me, but occurred in the practice of a New York doctor. She was a lady of the highest intelligence, and an artist. I got the account from her lips. She was disabled before her confinement, so as to be obliged to keep her room practically; she walked with her hands braced on her knees, sliding her feet along the floor. At time of confinement her labor was almost powerless, and she was unable to make expulsive efforts, until her physician, who recognized her true condition, fastened a strong band about her hips; then the labor progressed and terminated naturally. After labor she was treated by rest in her bed and the firm hip band. During her next pregnancy, her doctor applied the supporting band that I have before alluded to. This was used after the uterus arose from the pelvis. In the subsequent labor she had no difficulty, and although there was some relaxation she was able to be up and on her feet.

When the first two of this series of cases was reported before the Boston Obstetrical Society, Dr. Lyman reported one case of extreme relaxation, which occurred in his practice. It was treated with a strong band and perineal straps. His band was applied with strong buckles, so that it could be drawn very tight. He reported a perfect cure, with complete immobility. Dr. W. L. Richardson also reported a case coming under his observation in his office practice, which was evidently chronic. The patient ordinarily walked well, but was subject to fits of pelvic lameness (if I may so call it). There was a motion of one-half inch, as I remember.

Dr. B. F. D. Adams, of Waltham, reported a case of four months' abortion, in which this relaxation was very marked. This was the only one he had seen in his practice.

Mrs. J. P., Irish-American, aged twenty-eight; quite anæmic, delicate, and soft-fleshed. Has had two children. Confined May 30, 1882; pains slow. I left her with os dilated to size of a quarter-dollar, as there had been no pains for an hour. Gave directions to send for me at once if pains came on, being distant five minutes off. Pains came on, and *I* was not sent for, but an old woman *was*. When I arrived the child was born, and she had a smart flow, sending her pulse up to 120, and making her look white. I delivered placenta, and flowing ceased. She made a slow, but good recovery. The motion of the pubic bones was half an inch. I advised her to keep on a tight bandage for a month after. She complained of no soreness at the symphysis while in bed. I concluded that she was one of those cases that are not lamed or crippled by the great mobility of the pelvic bones, owing to the absence of pathological condition. But, on August 3d, while on a visit to her sick child, she complained to me of her inability to walk without pain at the pubes, and also, that there was a "snap or click with each step." I tested the condition by finger under the arch, while she stood alternately on one or the other leg. I found a good half-inch motion; also a crepitus, like the slipping of a dislocated bone into place. I ordered cold bathing, massage, and a good, strong, five-inch band, with perineal straps, fastened very firmly. This gave her comfort at once, and, after a year, she ceased to complain, and did her work over stairs without trouble.

She is able to take care of a family of four, and yet there is still great mobility.

I have never but once found this relaxation in non-puerperal or sterile women, or in virgins, and yet the number tested is so small as not to prove a law.

I recently tested the pubic joint in a young woman, just past thirty, and found a motion of one-eighth of an inch. She was unmarried, and, without doubt, had never been pregnant.

A NEW STUDY OF THE PELVIS.

A. I took an articulated female pelvis of the skeleton, fastened the junctions firmly with elastic rubber bands; marked two fine points on the *sub-pubic* arch, on each side of junction, $\frac{6}{20}$ of an inch apart; the *distance* between two fine points, one on each tuberi schii, was $\frac{9}{20}$ of an inch apart. Then separating the sub-pubic junction till the two points were $\frac{7}{20}$ of an inch apart (a separation of pubic junction of $\frac{1}{20}$ of an inch), and, fixing all fast, the distance between the two points on the ischia measured $\frac{8}{20}$ of an inch, $\frac{7}{20}$, or nearly $\frac{1}{3}$ of an inch. The above motion is represented by the separation of two radii, whose centre is at the centre of the symphysis, and terminations at the two points on the ischia. In the pelvis of my experiment, the rocking motion of the pubic junction was on the vertical centre, so that as I *opened* the sub-pubic $\frac{1}{20}$ of an inch, the supra-pubic *closed* $\frac{1}{20}$ of an inch.

Thus the result of a separation at the sub-pubic junction of $\frac{1}{20}$ of an inch *may* increase the distance between the ischiatic tuberosities $\frac{1}{3}$ of an inch minus, and $\frac{1}{10}$ of an inch separation, nearly $\frac{2}{3}$ of an inch — a very significant and important factor in the passage of a head through the outlet.

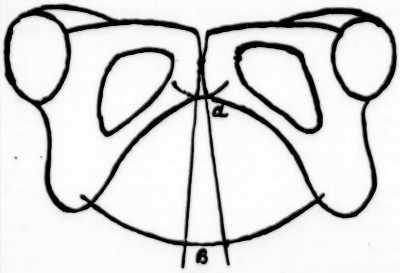

FIG. 3.

B. Second experiment. Having fixed the pelvis firmly in its normal condition, I measured the distance between two fine points, the one on the anterior margin of the coccyx, and the other on the inner margin of the pubic arch, at $\frac{10}{10}$ of an inch; then *flexing* the iliac (that is, motion upward) on a pivot through the *centre* of its junction with the sacrum, so that there was a motion forward at the sub-sacro-iliac junction of $\frac{2}{10}$ of an inch, and again measuring between coccyx and pubes, the distance was $\frac{17}{10}$ of an inch; or, in other words, an extreme *pivotal* motion of $\frac{2}{10}$ of an inch at the lower *margin* of the sacro-iliac junction meant an increase or decrease of the antero-posterior diameter of the outlet of $\frac{1}{8}$ of an inch minus, as the iliacs are carried upward or downward (flexed or extended) on the spinal column as a fixed point. In a word, by these experiments it is shown that, with a very slight relaxation of the pelvic ligaments and separation of the pelvic junctions, two new factors enter into the problem of the passsge of the head through the outlet: *First*, a slight separation ($\frac{1}{10}$ of an inch) at the sub-pubic junction *may* increase the lateral diameter between ischia $\frac{1}{8}$ of an inch. *Second*, a slight pivotal motion of iliacs on the sacrum, measured as $\frac{2}{10}$ of an inch at the sub-sacro-iliac junction, *may* increase the antero-posterior diameter of outlet $\frac{1}{8}$ of an inch.

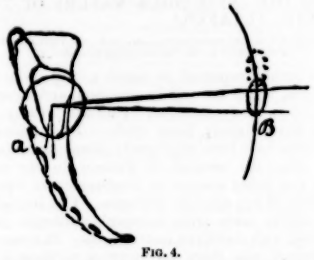

Fig. 4.

Practically, when the woman "braces her feet," she *opens* the antero-posterior diameter, and the child's head, under the force of uterine pains, *spreads* the ischia with all the advantage of leverage. No authors but Playfair and Duncan have recognized this fact in the slightest degree, and they only half; namely, the flexion and extension of the iliacs on the spinal column. No one that I ever heard or read of has tested the possible effect of a separation of the symphysis pubis on the distance between the ischiatic tuberosities.

C. Experiment third. With all the pelvic junctions fixed in their normal position, I measured the distance between two fine points, one on the anterior margin of the promontory, and one on posterior margin of symphysis, as $\frac{9}{10}$ of an inch; then *extending* the iliacs (that is, moving them downward), with a pivotal motion on the sacrum, through the *lower third* of the sacro-iliac junction, the amount of motion, as measured at the lower margin of this junction, being $\frac{2}{10}$ of an inch, I measured the distance between the promontory and pubes as $\frac{9}{10}$ of an inch, an *increase* of the antero-posterior diameter of $\frac{2}{10}$, or $\frac{1}{4}$ of an inch. When the pivot of motion was at the *centre* of the sacro-iliac junction, and not at the *lower third*, this increase of diameter was $\frac{3}{10}$ of an inch, so that a new factor enters into the problem of the passage of the head through the brim; and all those writers are wrong who say that a *great degree* of separation and relaxation is needed to enlarge the diameter of brim even a *line*. (Dewees says over $\frac{1}{4}$ an inch is required "to increase the diameter a line.")

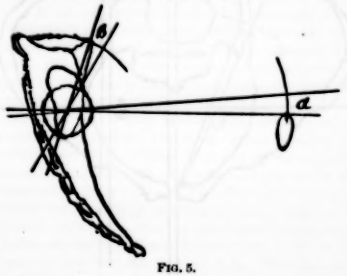

Fig. 5.

The new factor is this: that practically the *straightening* of the body and dropping of the pelvis on the spine tends to increase the antero-posterior diameter of the brim, and a very *small* pivotal motion of iliacs on the sacrum (which a small degree of relaxation will allow), *may* increase this diameter very essentially. A moment's consideration will show that the pressure of the head at the brim tends to carry the iliacs downward and the promontory away from the pubes. Again, according to the authors, it will need a separation of $3\frac{1}{2}$ of a line at the pubes to increase either diameter one line; being misled by the ratio of a circumference to a diameter.

D. But in experiment *fourth* I separated the pubic and two sacro-iliac junctions $\frac{2}{10}$ of an inch (it is reasonable to infer that this is possible in the lesser degrees of relaxation); the lateral diameter was increased $\frac{3}{10}$ of an inch plus, nearly $\frac{3}{10}$ of an inch. This can be shown to be correct geometrically, for this experiment was not the adding to a circle three segments, each $\frac{1}{10}$ of an inch, but, for instance, in the case of the sacro-iliac junction and the symphysis pubis, it was the separation of *two parallel lines* $\frac{1}{10}$ of an inch (see Fig. 6); and in the case of the *right* sacro-iliac junction it was the motion of a *radius* $\frac{1}{10}$ of an inch at its circumference; that is, at the sacro-iliac, and zero at its centre, that is, at the symphysis pubis; half way between centre and circumference, on the line of the *lateral diameter* of the pelvis, this motion is obviously $\frac{1}{10}$ of an inch minus. (See Fig. 6). So that in relaxation of the pelvic ligaments these four (4) factors come in, to facilitate the passage of the head through the brim: — *First*, the extension of the iliacs on the spine, which in effect carries the promontory away from the pubes, increasing the antero-posterior diameter; *second*, separation of the pubes; *third*, separation of the right sacro-iliac junction; *fourth*, separation of the left sacro-iliac junction. It is possible that the first may be within certain limits, $\frac{1}{4}$ inch for every $\frac{1}{10}$ inch pivotal motion at the sub-sacro-iliac junction; and that the sum of the last three *may* be $\frac{3}{10}$ of an inch *minus* for every $\frac{1}{10}$ inch of separation.

My observations through a series of 275 cases show a varying degree of mobility and separation in 75 *cases* out of every 100, and 70 *individuals* out of

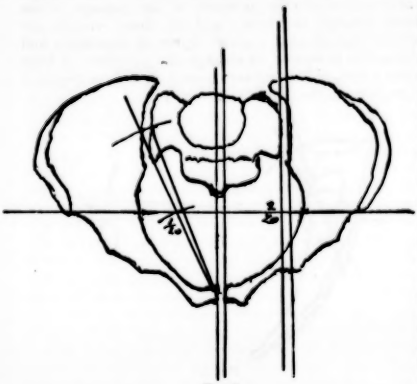

FIG. 6.

every 100. This new (to me) study demonstrates that a small degree of relaxation may increase very essentially both the lateral and antero-posterior diameters of the brim, and is a still more potent factor in increasing the antero-posterior diameter of the outlet and its lateral diameter between the tuberosities of the ischia. To the question, "Does the relaxation of the pelvic ligaments facilitate delivery?" the answer is — YES!

FINAL CONCLUSIONS.

My observations continued through a series of 300 cases in child-bed, as well as tests in quite a number of cases of virgins and sterile women, lead me to the following conclusions:

(1) That the presence of relaxation depends very much upon the strength of the bony and ligamentous structure of the skeleton; that is, it is more apt to occur in the woman of poor physique, the delicate, the soft, the "chicken-jointed." Some women can turn their fingers backwards and their ankles over sideways.

(2) That age does not determine its presence, at least the degree of it, as the following cases show.

44 years, 1 case, 1-4 inch motion.
42 " 2 cases, firm; 1, marked motion.
40 " 2, firm; 1, 1-2 inch; 1, marked motion; 1, 1-16.
39 " 1, slight m.; 1, 1-8 motion.
22 " 5, firm; 2, slight; 2, marked; 1, 1-4 inch motion; 1, 1-16.
21 " 2, slight motion; 1, 1-8 motion.
20 " 1, marked motion.
19 " 1, slight; 1, 1-8 motion.
18 " 1, firm.
15 " 1, 1-4 inch motion.

The age of observed cases ranges from fifteen to forty-four.

(3) It is not constant, but a degree of it is natural at time of labor, and may exist during pregnancy and even in the early months.

(4) There may be great motion and no lameness or impairment of walking power. Various authors testify to the contrary.

(5) There may be a small degree of motion and great lameness. Baudelocque, page 31, says, "We should be in the wrong if we supposed that such a state of weakness and pain always denotes great disorders in the junction. I am convinced that this may be a consequence of a very small separation or of the slightest movements between the ossa innominata."

(6) Lameness depends upon pathological condition of the junctions, pubic and sacro-iliac.

(7) Pain at the sacro-iliac junction of one side proves that on that side is the pivotal motion of the iliac on the sacrum. It may occur in non-puerperal females, in sterile and virgins.

(8) Patients may recover from a most serious condition of lameness without treatment, as in my third case.

(9) The most careful treatment, with all the aids that wealth can bring, may not restore firmness to the pelvis, as in my first case.

(10) Many a case of lingering disability after confinement, with what the doctor considers vague complaints, may have been due to this cause, and it is well, when you cannot find out "what is the matter," to test the condition of the pelvic ligaments.

(11) A small degree of relaxation or separation may facilitate delivery, and may be the factor that saves the use of forceps.

(12) As I am not bigoted, a further examination of the next series of 300 cases may change many of the above conclusions.

ABSTRACT OF A PRELIMINARY REPORT OF EXPERIMENTAL RESEARCHES CONCERNING THE INFECTIOUS NATURE OF TRAUMATIC TETANUS.[1]

BY EDWARD O. SHAKESPEARE, A.M., M.D., OF PHILADELPHIA,
Pathologist to the Philadelphia Hospital, etc.

THE author reported in detail a long series of experiments, which are still in progress, and announced the results already obtained. Upwards of fifty inoculations have already been made. Two methods of inoculation have been employed: intra-cranial inoculations, after the method of Pasteur in the case of rabies, and subcutaneous or inter-muscular injections by means of hypodermic syringes. The inoculations were always made with thorough antiseptic precautions, and with sterilized instruments. In none of the experiments was there any sign of accidental infection, such as suppuration, etc. The material used for inoculation was, in general, obtained from the medulla or the spinal cord, and cultures in neutral or slightly alkaline flesh-glycerine-agar, as recommended by Roux for the culture of tubercle bacilli. The tetanus material was taken, under aseptic precautions, from a horse and a mule dead of traumatic tetanus in the veterinary department of the University of Pennsylvania, the brain, medulla, and cord being removed one and three hours, respectively, *post-mortem*, and immediately kept on ice until used. The inoculation material was, in general, prepared in the following manner: A small piece of the medulla or cord was thoroughly rubbed up in sterilized, distilled water; after the solid particles were allowed, for a few minutes, to subside to the bottom of the vessel, the opalescent emulsion thus obtained was drawn off by means of sterilized pepettes, and placed in small, sterilized vials until used, never having been thus kept longer than three hours before inoculation. Eight control experiments were made.

The author concludes his paper as follows:

RÉSUMÉ OF RESULTS.

First Series. Eight rabbits were inoculated, sub-dura

[1] Read in the Section on Pathology of the Ninth International Congress, September 6, 1887.

cerebri, of a horse dead of tetanus, between August 1st and 18th, inclusive. The rabbit inoculated directly from this horse showed the first symptoms of tetanus within fifteen hours, and died of well-marked tetanus within forty-eight hours after inoculation. Both the period of incubation and that of death became markedly shortened in continuing the inoculations from rabbit to rabbit.

Second Series. Four rabbits were inoculated, sub-dura cerebri, from the same medulla of horse. The rabbit inoculated directly from the horse showed the first symptoms of tetanus within twenty hours, and died within forty-eight hours after inoculation. Continuing the inoculation from rabbit to rabbit, the period of incubation and of death became markedly shortened.

Third Series. Four rabbits were inoculated, sub-dura cerebri, from the same medulla of horse, after it had been kept on ice a day longer. The rabbit inoculated directly from the horse showed the first symptoms of tetanus within twenty-four hours, and died within forty-eight hours after the inoculation. Continuing the inoculations from rabbit to rabbit, the period of incubation and of death became markedly shortened.

Fourth Series. Three rabbits were inoculated, sub-dura cerebri, from the medulla of a mule dead of tetanus, with the same results as in the previous series.

Fifth Series. Seven rabbits were inoculated under the skin and into the muscular tissue of the back, from the medulla of the horse above mentioned. One died within eighteen hours, and another died within ten days, but neither of them showed any sign of tetanus. A rabbit inoculated sub-dura cerebri from the medulla of the latter, on August 15th, is still living and well on September 4th.

Sixth Series. A rabbit, which had been inoculated under the skin directly from the horse on August 1st, was, eight days afterward, inoculated sub-dura cerebri from the medulla of the last rabbit of the third series. It became sick and died promptly of tetanus, within the shortened period. A rabbit inoculated sub-dura cerebri from its medulla showed signs of tetanus within twenty hours, but did not die until five days after inoculation.

Seventh Series. Six rabbits were inoculated, sub-dura cerebri, from emulsions of spinal cords of rabbits which had died of tetanus within the short period above mentioned. These cords had been treated in a manner similar to that employed by Pasteur for the attenuation of the virus of hydrophobia, during periods varying from three to fifteen days. Five of them died of marked tetanus, the symptoms appearing, and death occurring, within periods longer than those of the corresponding rabbits from which the medulla had been taken, and usually proportional to the length of time the cord had been drying. One of the six showed doubtful symptoms, but, nevertheless, very promptly died.

Eighth Series. A rabbit was inoculated, sub-dura cerebri, from the medulla of a rabbit which had died after inoculation from the cord which had been fifteen days drying. It showed the first signs of tetanus in forty hours, and died of tetanus seven days after inoculation.

A rabbit was inoculated sub-dura cerebri from the cord which had been drying fourteen days, and it died of tetanus in twenty hours. A rabbit and a cow were inoculated sub-dura cerebri from its medulla. The former quickly died of marked tetanus. The latter died without marked symptoms within two days, and from the autopsy it seemed probable that injury to the brain had been the cause of death (there had been great difficulty in performing the operation of inoculation). A young rabbit, inoculated sub-dura cerebri from this cow's medulla, died within sixteen hours, but showed no signs of tetanus, and another rabbit inoculated sub-dura cerebri from the medulla of this rabbit August 27th, is still living and quite well September 4th, never having shown any signs of illness.

Ninth Series. Three rabbits were inoculated sub-dura ceribri September 1st, from spinal cords of tetanus which had been drying respectively twenty-three, twenty-seven and twenty-eight days (these cords were the same as those which had been drying longest, mentioned in the preceding seventh series). The rabbits inoculated from the twenty-third and twenty-eight-day cords showed no signs of illness up to the time of the last observation, September 4th. The one inoculated with the twenty-seven-day cord for the first time showed stiff jaws and difficulty in eating on the afternoon of September 4th.

Tenth Series. Three rabbits which had been inoculated under the skin on the 19th of August, and had remained perfectly well, were inoculated sub-dura cerebri, September 1st, from the same cords mentioned in the ninth series. The rabbit inoculated with the twenty-third-day cord was found dead the next day, but it showed no signs of tetanus either externally or at the autopsy. That of the twenty-eight-day cord showed stiff jaws and would not eat for the first time on the afternoon of September 4th. That of the twenty-seventh-day cord showed no signs of illness up to the last observation, September 4th.

Eleventh Series. Three rabbits were inoculated sub-dura cerebri, August 31st, from cultures started from the horse's brain August 1st and renewed once, namely, on August 20th. One of them has remained quite well up to the last observation, September 4th. One remained quite well until September 2d, afternoon, when it showed intermittent trismus and indisposition to eat. This condition continued up to date of last observation, September 4th. One showed for the first time slight signs of tetanus September 3d, and had them also up to date of last observation, September 4th.

Twelfth Series. A trial attempt was kindly made for me by Dr. L. Wolff, Demonstrator of Medical Chemistry in the Jefferson Medical College to isolate a ptomaine from the brain medulla and cord of the mule and cow above mentioned. The Stass-Otto method was more or less closely followed.

The product obtained from the mule was injected under the skin of the back of two rabbits. They became very ill within twenty minutes, being slightly paralyzed and exceedingly restless, frequently getting down flat on the belly and up again and jerking the hind legs up, but they showed no marked convulsive movement or trismus. They entirely recovered within six hours.

The product obtained from the cow produced but little and only very transient and indefinite effects.[2]

[2] Several autopsies of the tetanus animals were made, and they invariably showed intense congestion of the lungs, trachea and kidneys. Sometimes there was congestion, oftentimes none at all, of the central cerebro-spinal nervous system. The mucous membrane of the stomach was apparently normal.

Conclusions drawn from the author's personal researches.

(1) Traumatic tetanus of the horse and mule is, at least sometimes, if not always, an infectious disease, transmitable to other animals, and therefore possibly also to man; and during the progress of this disease a virus is elaborated and multiplied which is capable of producing the same infectious disease in some other animals when placed beneath the dura mater of the cerebrum.

(2) This virus is contained in the medulla and spinal marrow of the animal suffering the disease. It is, like the virus of hydrophobia, capable of being strengthened in virulency by inoculation sub-dura cerebri from rabbit to rabbit, and, like the virus of hydrophobia is capable of attenuation by exposure for a sufficient time to the action of dry air at a temperature of summer heat, and still again like the rabic virus, its effects are far more intense when the virus is inserted beneath the dura-mater cerebri than when injected beneath the skin or between the muscles of the back.

The author reserves his conclusions concerning a prophylactic effect of inoculations of the attenuated virus, until the completion of experiments which are at present in progress.

Conclusions drawn from the author's experiments when correlated with those of Nicolayer, Carle and Ratone, Rosenbach, Ferrari, Flügge, *et al.*

Traumatic tetanus of the lower animals and of man, at least sometimes, possibly always, is a specific infectious disease due to the action of a specific infectious virus which exists in the tissues at the seat of infection, in the blood and in the central cerebro-spinal nervous system.

In view of the experimental evidence which we possess at present and of many unassailable observations of many surgeons and veterinarians, there seems to be ample warrant for the admission that not infrequently tetanus in man is acquired directly and indirectly from some of the domestic animals, notably the horse, which surround him.

THREE CASES OF DYSPEPSIA.[1]

BY ELBRIDGE G. CUTLER, M.D.

Of the cases I am about to report, two illustrate the favorable result sometimes obtained by attending carefully to the diet. The other shows the advantage which may be gained at times by simply washing out the stomach.

CASE I. Miss P., aged twenty-two, had suffered from dyspepsia somewhat for five years, or ever since she had been a school-girl, and of late it had gradually become much worse. Her menstruation had been regular up to the previous spring, (she was first seen Dec. 23, 1882). It then became irregular, and since August of that year she had not menstruated at all. For several years her bowels had been constipated. All kinds of food after a time hurt her. She had got to taking less and less and changing from one thing to another, till she hardly knew what she could do in the way of digestion. She had been under treatment most of this time. She suffered from curious sensations in the head, due, I thought, to anæmia, and complained of having a veil over her eyes. She was pale, anæmic, emaciated, her sleep was disturbed by restlessness and dreams, the bowels were constipated. She had to keep her bed most of the time. The pulse was 80, small, soft, and regular. The cardiac area of flatness was normal, physical signs in the chest negative, except there was a venous hum in the neck. The epigastrium was not sensitive to the touch. The stomach as determined by percussion was rather small. The weight was about ninety pounds. The amount of urine in twenty-four hours was about one and a half pints. It contained much mucous and flat epithelium and a trace of albumen.

I began the treatment with raw oysters, milk, and milk and raw eggs, and a little Carlsbad salts in hot water in the morning; gradually increasing the quantities of food for four days, when she began to sleep better and I added dialysed iron. Two days later, I gave in addition malt and buttermilk. Two days later, half a pint of water was added. A few days later I gave the syrupus hypophosphitum compositus. On January 4th, the bowels had been doing very nicely and I added rock-salt to her morning bath. She was then passing one quart of urine in twenty-four hours. On the 17th the pulse was stronger, there was more color in the face, she was getting fatter. She was taking food and drink in sufficient quantity at regular intervals which was fairly well digested. The bowels were attended to daily. I then added passive movements to the treatment. The 25th she was sleeping well all night, and had had no trouble with food for several days. The dialysed iron was changed to ferrum reductum, and emulsionized cod liver oil was added to the treatment once a day. February 17th, had done splendidly in every way. Menstruation had come on since the last visit, and food had disagreed a little during that time. On March 28th, I made out a regular diet list and left her in the hands of her nurse, a most faithful, conscientious person. On July 26th, I saw her and found that she weighed one hundred and forty pounds, (she was five feet seven inches tall), she was looking remarkably well, and said she never felt better in her life. Since then, with the exception of occasional slight temporary fits of dyspepsia, she has remained perfectly well.

CASE II. Miss H., aged eighteen, as a child was always well and strong. Menstruation began regularly at the age, I think, of fourteen, and continued till eighteen months or two years ago, when, having had dyspepsia for two years and being run down, the menses ceased. Her food had hurt her constantly all this time and one article after another was omitted from her dietary till at last it became very meagre. She was sent to the mountains and the seashore without avail. The drug treatment consisted of pepsin, soda mint, hydrochloric acid, and some other things, and finally peptonized milk was added. In spite of what was being done she steadily became worse during the twelve months before I saw her, which was in November, 1885, so that at that time though five feet and eight or ten inches tall, she was very much emaciated, and weighed but 86½ pounds, when in ordinary street costume. The extremities were cold the whole time, the face was pinched, the hands suggestive of bird's claws. She was very restless, wanting to be constantly on the move, she slept poorly, had bad dreams, suffered from

[1] Read at the annual meeting of the Suffolk District Medical Society, April 30, 1887.

headache, and on starting to do anything she would stand about in a hesitating, helpless way which was at times almost painful to witness. She was rather listless, and although answering questions about her health readily, she evidently regarded the inquiries as a bore. Little positive could be made out in reference to the digestion of different articles of food by questioning, except that it was generally bad. Physical examination of the chest revealed nothing abnormal.

Forty-four ounces of urine were passed in twenty-four hours, and except an increase in the amount of indican and mucus, and a diminution of about one-quarter from the average amount of urea passed in health, it was not remarkable. The abdomen on physical examination was not abnormal. The stomach was diminished in size. There was slight epigastric discomfort on pressure. The skin was rough and scaly, especially on the face and limbs.

I began by prescribing a fixed diet for the next three days and before each meal a dose of gentian, and every morning a dose of Carlsbad salts in hot water to push on the contents of the stomach and prepare the way for the food of the day. I gave the Rabuteau's dragees and a preparation of maltine as a drink with breakfast. I gradually added to the dietary, seeing her every three days for a time, and by degrees lengthened the interval of my visits. On January 4, 1886, the weight was 88 pounds. On January 7th, I changed to Sedleitz Chanteaud,[2] and soon after began Koumiss. On February 20th, she was taking Sedleitz Chanteaud in the early morning, quassia before meals, Koumiss with dinner and supper, emulsionized cod-liver oil after meals, one Rabuteau dragee in the morning, peptonized milk between breakfast and dinner and between dinner and supper, and malt with breakfast. She weighed that day 97 pounds. By March 20th, she had reached 100 pounds. By April 17th, 107 pounds.

May 1st, she weighed 106 pounds; May 15th, she weighed 108 pounds; June 12th, she weighed 112½ pounds.

July 26th, she took ordinary meals with Koumiss and peptonized milk added, other things being omitted. September 10th, she weighed 126½ pounds. The menstruation had returned. October 23d, she weighed 136 pounds, and as that was the limit I had set, I omitted all treatment except that I insisted on her maintaining a certain proportion of the different kinds of food. April 17, 1887, I saw her, and found that she had been well all winter, had gone out to balls, parties, theatres, etc., and then weighed, in her spring costume, 130 pounds, which was ten pounds more than she desired.

These two cases are good examples of a type we frequently see, occurring chiefly in young women of the better classes who have recently passed from the school-girl romping period of good health, to the young lady period of private lessons, insufficient exercise, improper diet, constipated bowels, painting and general culture, the pernicious club (sewing or social), and afternoon teas. They first get deranged by insufficient outdoor exercise, and by an improper proportion of albuminates, fats and sugar or starchy foods in their diet, and by their general unhygienic life. The next step, which is a short one, is to indiscriminate or illogical dosing, and from that time the mischief is accomplished. The cases also show the absolute necessity of accurately knowing from personal observation the exact condition of the patient's digestion. By this means only, by patient and persistent observation, can one know whether the proper proportions of the different articles are consumed and be ready to supplement any deficiency. A drug treatment without such knowledge I should strongly oppose. A second very important point, it seems to me, is the giving of a certain amount of food, beginning with a little less than is the proper average, and gradually increasing the amount, and at the same time insisting on the patient's taking it in spite of pain or other discomfort at first. I attach considerable importance also to the daily giving of a proper dose of Carlsbad salts or Sedleitz in the early morning.

Case III. Dan. McNeil, aged thirty-five, married, a machinist by trade, born and living in Boston, came to the Massachusetts General Hospital, November 10, complaining of gastric trouble. There was constant pain in the epigastrium a short time after eating, eructations of gas, and often, at some time in the day, an attack of vomiting, most frequently occurring in the morning. These symptoms had existed for five months, but had gradually become worse, and were associated with constipation. He was frequently detained from work. A careful physical examination of the chest showed no abnormality. The vomitus was very frothy. The abdomen was fairly prominent; the stomach, on percussion, certainly was not enlarged. There was a little tenderness in the epigastrium, at the lower end of the xyphoid cartilage. As it was believed that fermentation was occurring in the stomach, he was advised to allow the organ to be washed out. On full explanation, he readily assented, and, accordingly, a tube, such as is shown, was passed in, and one quart of warm water was carefully poured in, to which a teaspoonful of boracic acid had been added: part of this fluid was withdrawn by syphonage once or twice, and then nearly one pint was left in the stomach, to act as an anti-ferment. One week later, the patient reported again as having been very much improved. The gas was no longer passed, pain was much less; there had been no vomiting. He had gone back to his work from the hospital that day, and had pursued it steadily since. So much pleased was he with the effects of the treatment, that he had brought back with him a friend similarly affected for like relief. The procedure was repeated, and the patient went to work. On the 24th, he reported as being practically well. The washing out was performed again, and he was discharged well.

The mechanical treatment of gastric disorders was made use of by the ancient Greeks. In the time of the Roman emperors, a number of instruments were in use to facilitate vomiting, used chiefly in cases of poisoning. They consisted essentially of a leather cap to go on the finger, or a feather with which to irritate the pharynx.[3] At the end of the seventeenth century, the direct treatment of the gastric mucous membrane was in vogue in the use of the stomach-brush. The handle of the instrument, twenty-six inches long, consisted of a twisted brass wire, wound with silk thread. On the lower end of it was a small brush, three inches long, two inches broad, made of goat's beard or horse-hair.[4] In the eighteenth century, the elastic catheter

[2] A quite pure French preparation in form conveniently handled.

[3] Leube. Magensonde, Erlanger, 1879.

[4] Leube. Loc. cit.

was recommended for the purpose of exhibiting food and drugs. Hunter used hollow bougies or flexible catheters for this purpose. Soon followed the first attempts at emptying the stomach of its contents by means of a pump. The English surgeon, Bush, was probably the first who pumped out a stomach. In cases of opium-poisoning, he fastened an elastic, hollow tube to an ordinary syringe, injected water, and then pumped out the diluted contents of the stomach.

In the second decade of the present century, different sorts of stomach-pumps were devised by several different persons, and, as sounds, either gum-tubes ending in a perforated ivory knob, or flexible elastic tubes with rounded ends and two openings at the sides, were used. These instruments and methods were never in general use, and soon were forgotten. Our own countryman, Dr. Sommerville, of Virginia, proposed, in 1823, to syphon out the stomach, and took a flexible tube, four feet long, to wash it out, one end being arranged to pass into the stomach, and the other end being armed with a funnel.[5]

To Kussmaul, the German, however, belongs the honor of first having called general attention to the benefits to be derived from the systematic use of the stomach-pump, in his work on the treatment of dilatation of the stomach, in 1867; and through him the mechanical method was introduced into general practice, and has become, since then, a more or less general procedure. Since Kussmaul's work, the progress has been made of using the syphon, instead of the pump, which must be regarded as a great advance, and due largely to Oser,[6] of Vienna.

The mechanical treatment of the stomach may be divided into three procedures: the catheterization of the œsophagus, the emptying of the contents of the stomach, and the local treatment of the gastric mucous membrane.

I. Before proceeding to *catheterize* the œsophagus, a careful examination of the cavities of the mouth and throat are to be made, to see, first, if the instrument can be passed at all. An abnormally narrow throat, very prominent tonsils, cicatrices, tumors, adhesions, may present an absolute bar to the passage of any instrument.

Quite as important is an accurate examination of the circulatory and respiratory organs, because severe, non-compensated, cardiac lesions, aneurisms of the aorta, advanced phthisis, present contraindications to catheterization, or, at least, demand extreme care, on account of the liability to spasm. Acute and chronic laryngeal catarrhs also interfere, for, as soon as one gets near the larynx with the catheter, an attack of laryngeal spasm may occur, which makes the patient, as well as the physician, think he is going to suffocate. The instrument is either the one of soft rubber, which I pass round, or a stiffer one, with a bell-mouth. The length of the tube is about thirty inches.

In passing it in, the patient sits with the head thrown slightly back and the mouth wide open, the index finger of the left hand is placed on the tongue, and the right hand passes the tube, wet with water, or better, milk,[7] to the back of the throat, and, the patient being told to swallow, the point of the catheter is passed down, so that the constrictors of the pharynx grasp the end, and the instrument is then rapidly pushed down during repeated acts of swallowing. Long breaths minimize the sense of choking often experienced. The tube must be passed, at least, twenty-eight inches, as eighteen inches represents the distance from the teeth to the cardiac end of the stomach (sixty or seventy centimeters is the rule). According to Penzold's investigations, a sound three-eighths of the length of the body suffices to reach the deepest part of the stomach.

The advantages of the soft tube are the almost impossibilities of causing injury to the œsophagus, as it bends and turns round or returns and does not perforate the tissues in case of meeting with an obstruction. It cannot injure the gastric mucous membrane when with ordinary care. It may be used to rouse the gastric muscular contractions without injury, which are of great assistance in syphonage.

The disadvantages are that it is sometimes grasped and compressed by the muscular tissue so that it cannot be passed, or its lumen becomes closed when it has reached the stomach, so that it is rendered useless for the purposes of syphonage. In this case the stiffer tube is to be used.

II. The emptying of the gastric contents.

(*a*) Solids and fluids. For this purpose the pump and the syphon are used. The pump is the ordinary one used for aspiration, and may be attached to the end of the flexible catheter. The chief disadvantage of its use is the danger of aspirating some of the gastric mucous membrane and tearing it off. It is, however, to be used when all the contents are to be removed unchanged for a chemical or microscopic examination, and in most cases of poisoning.

The simpler and easier method is the syphon, which must be at least two meters (six feet) long. The catheter is to be filled with water and passed in and then a tube of the same length and diameter may be attached to the outer end by means of a glass tube, and the lower end sunk below the epigastrium or to the ground, when the contents, such as will, may run out. Sometimes it will be necessary to let a little fluid run in, half a pint or less, in order to start the flow, or if a solid particle gets lodged, it must be dislodged by more fluid or the patient be made to cough, or the tube be removed, washed out and reinserted. A pint or a pint and a half may be needed, if much solid matter is present.

(*b*) If gas is present the tube must be passed in but 40 to 50 centimeters instead of 60 or 70, and the abdominal muscles brought into play either voluntarily or by kneading.

III. Irrigation of the stomach.

In most cases a simple washing out with fresh, cool water will suffice; in anæmic persons the water must be lukewarm.

The quantity is one pint to a quart, and it is to be allowed to run in and out until it returns clear. Or a solution of bicarbonate of soda, one drachm to the quart may be used if there be much mucus, or in cases of constipation sulphate of soda a drachm and a half to the quart of water. In some cases of chronic catarrh, alkaline waters, Carlsbad, Vichy, and so forth may be used with advantage, or the above mentioned solution of bicarbonate of soda, one to two per cent. or the same of sprudel salts. If the contents are very acid or fœtid, salicylate of soda, thirty to forty grains to the quart may be used to be followed by pure water. Resorcin one-half to three per cent. is rec-

[5] Leube. Loc. cit.
[6] Wiener Klinik., 1875.
[7] When vaseline or oil is used, an unpleasant taste is left in the mouth.

ommended (the latter per cent. seems to me to be too strong). Carbolic acid is dangerous. Permanganate of potash in weak, violet-colored solution and boracic acid one to two per cent. are also good in cases of fermentation. In cases of severe pain, suspensions of bismuth subnitrate, an ounce to the pint, and allowed to remain for a time in the stomach so as to deposit a layer of bismuth or chloroform water (aquæ chloroformi of the "United States Pharmacopœa") diluted one-half may be used.[8]

The best time to wash out is before the chief meal in the day, or three or four hours after breakfast. Some persons whose sleep is apt to be disturbed by pain caused by food are better treated at night. The kind of disease and the result obtained determine the number of washings to be made. Sometimes severe inflammatory symptoms have appeared afterward, or great tenderness of the stomach or vomiting. These complications I have never seen. The treatment should end when the digestion is essentially benefited and the digestive power greater, and when no mucus or undigested food is brought out (naturally the washing must be four or five hours after taking food). Some cases require but a few washings, while others demand it daily the rest of their lives.

Unpleasant symptoms seldom occur. At first the procedure may be difficult, later it is not so. Spasm of the larynx has not been very rare, or slight faintness perhaps in a few cases. The gastric mucous membrane has been torn off sometimes, usually not accompanied by much pain or hæmorrhage. Considerable hæmorrhage may occur in gastric ulcer or phthisis, or heart disease, and prove a bar to the use of the sound.

Indications. (*a*) For diagnostic purposes. To determine the size of the stomach, differentiate the transverse colon, to get the contents for chemical or microscopic examination. (*b*) For therapeutic purposes. To remove injurious substances, either those taken in, or those which have undergone changes, and to treat the diseased mucous membrane, and lastly to increase the diminished contractility of the stomach. It is, therefore, used in poisoning, especially by alkaloids, in acute and chronic catarrh, dilatation, ulcer, cardialgia, cancer with consecutive dilatation, and catarrh.

Contraindications. The existence of those diseases in which vomiting, if it be caused by the procedure, may prove harmful, proves a bar; as in hæmoptysis, in persons with atheromatous arteries, in those having a tendency to apoplexy, in aneurisms of the aorta and large vessels, in non compensatory heart lesions, in cases of weak or fatty heart, in advancing gastric ulcer or recent hæmatemesis.

By means of this method of treatment we may do a vast amount of good at times. Fortunately, it is the very persons who need most to be well in the quickest possible time, namely hospital and dispensary cases, who make the least objections to its use. In my experience, at least, the better class of patients, to whom the element of time in recovery is no object, view the procedure with distrust, apprehension and disgust. They prefer the longer and ordinary methods of treatment, and are constantly making future appointments for the operation and not fulfilling their part of the agreement when the appointed time arrives.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

HERBERT L. BURRELL, M.D., SECRETARY.

April 30, 1887, the President, Dr. G. B. Shattuck, in the chair.

Dr. E. G. Cutler read a paper on

THREE CASES OF DYSPEPSIA.[1]

Dr. F. Minot thought that dyspepsia was a less common disease now than formerly, owing to the improved hygienic condition of life, the better food and better cooking of the present time. The cases reported by Dr. Cutler might be divided into two kinds. The first two were examples of failure of nutrition consequent upon a chlorotic condition, as shown by the improvement following the administration of iron, and the careful regulation of the diet. The last case seemed to him to be one of chronic gastric catarrh, with abundant secretion of mucus, which by its alkaline reaction neutralizes the acidity of the gastric juice, besides enveloping the food and protecting it from the latter. It is this condition especially which leads to dilatation of the stomach, and fermentation of its contents. Dr. Minot had had no personal experience in irrigation of the stomach in these cases, but he believed it was by far the most effectual mode of treatment; the stomach is speedily relieved of the mass of fermenting material, together with the mucus, and the lining membrane can be subjected to appropriate local treatment.

Dr. F. C. Shattuck expressed his interest in the two first cases of the reader, cases which show well what can be done by intelligent and painstaking treatment. Both patients had been long sufferers, had been under the care of physicians, but had not been placed upon, or else had not been willing to undergo, treatment suitable to them until they came under Dr. Cutler's care.

But the third case is one for the report of which the Society should feel especially grateful to Dr. Cutler. The simple operation of washing out the stomach is one which has not received the favor and attention here in Boston which is its due. As was remarked by the reader, the procedure is repugnant to many people, especially those in comfortable circumstances, and members of this class generally prefer some more tedious method of treatment which has less disagreeable associations. Those who consent to try the tube find it less unpleasant than they expect, especially after they have used it several times. Some patients of the speaker have very soon learnt how to swallow the tube themselves.

Some years ago, when making a visit to St. Luke's Hospital in New York, with Dr. Kinnicutt, the speaker saw there several patients whose stomachs were being washed out. One was asked whether the process gave her any relief, and replied: "Oh, doctor, my stomach wants it every morning just as a baby does his bath."

The reader seemed to imply that the use of the tube is contraindicated in cases of tuberculosis in the stage of cavity formation, a view from which the speaker dissented. We are all familiar with Debove's treatment of phthisis by hyperalimentation, large

[1] See page 252.

quantities of nourishment being poured into the stomach through the œsophageal tube. In some cases of nervous dyspepsia and vomiting the speaker had obtained brilliant results by introducing the tube into the stomach and pouring down a quart of peptonized milk with raw eggs, once or twice a day. The stomach can often digest more food than it is possible to swallow in the ordinary way. A patient recently under treatment, a neurasthenic with pronounced gastric symptoms, could not be brought beyond a certain point under the ordinary methods; but gained greatly in all respects from the time that the use of the tube was begun, increasing seven pounds in weight in two weeks. Insane patients are not the only ones to whom the procedure is applicable.

DR. E. S. BOLAND said that in washing out the stomach, in four cases I have passed the flexible tube through the *nose*. Passed in this way the patient can speak, is less liable to gag or vomit, and there is no more, if as much, danger of entering the larynx as when the tube is passed by the mouth. The finger need not be used to guard the larynx; so, if the patient is unconscious (as in case of poisoning) obstinately suicidal or insane, its advantage is manifest, as resistance is impossible.

We are liable to forget the capacity of the nostril. In children under eight, a three-eighth, and in adults a five-eighth inch soft rubber tube is admitted in almost every nose. Occasionally one nostril, from deformity of the septum, will be too narrow, in which case the other will be found ample. In one insane patient I have passed the tube through the nostrils more than three hundred times in the course of three or four months, feeding without injury or special suffering. Entering by the nostril the distance to the stomach may be a trifle greater, but practically the exact estimate of the distance is seldom needed, as almost always a variable collection of gas or air is present in the summit of the gastric cavity. As soon as the eye of the tube reaches this, it escapes *audibly*, and we know the stomach has been entered. This may alarm a novice who fears he has got into the air passages, especially if, as sometimes occurs, air is alternately drawn in and expelled, owing, may be, to the patient's struggles or restraint of him by the nurse. In this connection might be mentioned the curious fact often seen in feeding insane patients whose digestive function is vigorous — namely, a vigorous suction action on the part of the stomach out of all ratio to the hydrostatic pressure.

DR. STUART stated that he had lately seen a German who had previously had his stomach washed out in Vienna, and learned to perform the operation upon himself. In Boston, in lieu of an Oser stomach-tube, he had taken a piece of ordinary rubber hose (such as is used on gas lamps) about five feet long, and had used it as a siphon for washing out his stomach. He not only inserted the tube unaided, but he would fill his stomach through the tube and siphon off the fluid with great dexterity. Dr. Stuart mentioned the case, thinking it suggested an expedient that might prove of value in an emergency.

DR. C. M. GREEN called attention to the value of the soft rubber catheter as a means of introducing nourishment directly into the stomach of premature infants too feeble to suck or perhaps to swallow sufficient nourishment when fed with a spoon. The method was devised by Tarnier and called by him "gavage."[2] A No. 18 catheter (French scale) is passed about six inches down the œsophagus; the nutrient fluid, preferably breast milk, is introduced by means of a small glass funnel, and flows into the stomach by its own weight. Of course, suitable measures must also be adopted to maintain the bodily heat. By the combined use of gavage and the couveuse, or hot air cradle, Tarnier has saved infants born soon after the sixth lunar month.

DR. BLODGETT stated that an accident of peculiar character had been brought to his notice by a practitioner well known to the members of this Society, in which one of the dangers attending the passage of anything in the shape of a stomach-tube were illustrated. The patient was a woman, who was in a state of great prostration from an exhausting disease. In view of possible collapse, the physician had directed the administration of an enema of broth.

The nurse misunderstood both the direction of the physician, and that in which the broth was intended to go, and in her desire to relieve the patient, she introduced the point of the syringe into the mouth of the patient, passed it into the throat, and presumably into the glottis, and succeeded in drowning the patient with the broth which was intended for an injection.

DR. CUTLER said, in answer to Dr. F. C. Shattuck, that he should have specified more exactly the contra-indications in phthisis which was where there was advanced disease with laryngeal complications. In the earlier stages or where there was no throat symptoms he sometimes used the tube to convey food as suggested.

In answer to another gentleman who referred to the use of gas tubing, he would state that this very kind of tubing was the sort originally suggested as best fitted to use in catheterizing the stomach.

DR. JOHN HOMANS, 2d, showed a fibroid tumor of the uterus, weighing twelve pounds, which was removed the day before by Dr. John Homans. The patient was between thirty-five and forty years of age, and had suffered intensely with pain and the discomfort of the weight of the tumor. There had been frequent and considerable hæmorrhages; a year ago the uterine cavity had been scraped out by some practitioners; this had been followed by severe hæmorrhage and collapse which nearly proved fatal. The abdominal incision extended from two inches above the umbilicus to the pubes, and the stump wass ecured extraperitoneally, and touched with the per-chloride of iron. The condition of the patient on the day following the operation was, temperature 100° and pulse 90 to 100.

DR. B. F. DAVENPORT said, probably most of us have noticed in many of to-day's journals published in this city, the striking profile trade-mark of "Kaskine," the new quinine, as its manufacturers, the Kaskine Company of New York City style it. The pamphlet which accompanies the preparation says that it is a non-toxic phenol, prepared from pure bitumen, and that it is a non-secret medicine, entirely free from poison, which "entirely does away with the use of that terrible destructive drug, quinine." It further says that "though not vermin-covered, humanity is often, alas, vermin-lined," and that "until the recent great scientific discovery there was no known medi-

[2] For a full description of this method see the Amer. Jour. of Med. Sciences, January, 1886, or Vol. cxiv., No. 8, page 174 of this Journal.

cine that could reach and destroy these germs; but the power which the hound has in scenting footsteps which no human skill, can detect is the power possessed by Kaskine," and that "under its influence there can be no diseased conditions."

Such are its modest claims, yet a short time ago I had occasion to examine the preparation chemically with the following results: The sugar pellets averaged a little less than one grain in weight, and one hundred of them contained together about one-twelfth grain of quinine, about one sixtieth of arsenic, and a trace of carbolic acid. And I was told that by taking a whole bottle full of them at a time for the single test one could also find in them a trace of corrosive sublimate. Thus all four of the active antiseptics claimed for the preparation by its manufacturers are accounted for, and each can draw his own conclusions as to whether their claims for its great medicinal virtue are likely to be true.

The PRESIDENT said that Kaskine had been put on the market some two years ago, and that it had been endorsed on the tradesman's circular by the names of a number of prominent New York practitioners. Certain charts were appended as showing the antipyretic action of the drug, and these charts purported to come from Bellevue Hospital. Some time ago there was a communication published in the *Boston Medical and Surgical Journal*, to which he would refer those who cared to look up the subject.

AMERICAN DERMATOLOGICAL ASSOCIATION.[1]

ELEVENTH ANNUAL MEETING.

AFTERNOON SESSION.

CLINICAL NOTES ON PRURITUS,

by DR. L. D. BULKLEY, of New York.

Pruritus or itching, is an extremely common symptom resulting from various causes, many of which are recognizable. There are a certain number of cases in which the pruritus appears without apparent cause. It was only this last group of cases that were considered. In the present state of knowledge, it is not possible to determine the exact lesion in these cases. Pruritus may be defined as a functional disturbance of the nerve elements of the skin, resulting in itching not dependent upon local irritation or local lesion. Out of a total of 5,000 cases of general skin diseases, the author had records of eighty cases of pruritus, a proportion of about 1.75 per cent. Thirty of the patients were females and fifty males. In the majority of cases there was some chronic disease, such as gout, albuminuria and chronic bronchitis, or marked evidences of lowered general vitality. The cases were classed under the following heads, according to frequency, pruritus hiemalis, pruritus genitalis, pruritus ani, pruritus vulvæ, pruritus scroti and pruritus senilis. In quite a number of instances the pruritus proved rebellious to treatment.

Temporary benefit was obtained in some cases, while in others no relief resulted from treatment. The author was of the opinion that in many cases the condition resulted from reflex irritation.

In connection with this subject the author referred to 115 personal observations which he had made. These consisted in the production, either accidentally or intentionally, of a point of irritation in some part of the body and in noting the point at which itching was experienced. The observations were made with the object of determining whether or not there were crossed reflexes. The reflex sensations cannot be induced at will, but seem to be more readily brought about when the body is fatigued; eighty-four of the observations related to the right side of the body, while thirty-one related to the left. In all but three instances, the reflex occurred on the same side as the point of irritation. These three exceptions were as follows: irritation on inside of right knee followed by reflex itching felt over the left scapula; irritation of the right thigh, four inches above the knee, produced reflex sensation of itching at the insertion of the left deltoid; irritation of the left heel followed by reflex itching over the right side of the pubes. Irritation in the same locality will frequently on different occasions produce reflexes in entirely different localities. The results have been so varied that it is impossible to classify them in definite groups. The author offered these notes as a slight contribution which might stimulate to renewed energy in the study of pruritus, with the view of determining the causes of its occurrence and of its obstinacy.

CLINICAL NOTES ON PEDICULOSIS.

by DR. F. B. GREENOUGH, of Boston.

The speaker had been induced to examine this subject on account of the fact that the statistics of the Association had shown that there was a greater proportion of cases of pediculosis reported from Boston than from any other city. He had found, taking the statistics for nine years, that the proportion of cases of pediculosis to the total number of cases of disease of the skin was, in Boston 5.5 per cent.; in New York 3 per cent.; in Philadelphia 3.33 per cent.; in Baltimore, 2.12 per cent.; St. Louis, 1.5 per cent.; in Chicago 3 per cent.; and in Canada 0.3 per cent. In 1884, New York reported, out of a total of 2,737 cases of skin disease, no cases of pediculosis of the head. During the same year the number of cases of pediculosis pubis reported from Chicago equal that reported from all of the other cities. The only explanation of this fact that can be offered is that the difference is more in observers, than in the number of cases of the affection. An observer in one city may put under the head of eczema capitis, a case which would be considered in Boston as one of pediculosis capitis. There are three different forms of pediculi, the pediculus capitis, the pediculus corporis, and the pediculus pubis. Thus pediculi are rarely seen except in their own locality. The presence of pediculi capitus in large numbers causes cutaneous trouble. So far as the efflorescence goes, the eczema thus induced is identical with that due to other causes, but the distribution and other conditions make the diagnosis easy. The speaker had only in one instance noted the pediculus corporis on the skin, and he thought it possible that they may feed without leaving the clothing.

DISCUSSION.

DR. L. H. DUHRING, of Philadelphia. My experience with a certain number of cases of pediculi vestimentorum is that they do leave the clothing, and I have seen them feeding upon the skin.

DR. J. C. WHITE, of Boston. In regard to diag-

[1] Continued from page 234.

nosis, I have seen cases in which I have been able to make the diagnosis without looking at the head. In children where there is an eczematous eruption in certain respect resembling impetigo contagiosum, located around the orifice of the mouth, the nostrils and the lobes of the ear, I make the diagnosis of pediculosis of the scalp.

Another practical point is that pubic lice do not always confine themselves to one locality, but may be found in different parts of the body. Careful examination will show them that not only in the axilla but also on the lower extremity. In one case, that of a child, I found the pubic lice in the hair of the head. If the treatment is limited to the pubic region the result may be unsatisfactory.

In the treatment of pediculosis of the pubic region and of the head I always use crude petroleum. This does not produce the slightest irritation upon the most inflamed surface. It should be allowed to remain in contact with the hair for two or three hours.

DR. P. G. UNNA, of Hamburg. In Vienna it is the custom to consider every case of pustular eczema of the head and scalp as due to pediculi, without making any further examination. This is, I think, a mistake. Although pediculi may be present in these cases they may only be secondary manifestations, resulting from the good feeding-ground furnished by the diseased skin.

DR. J. N. HYDE, of Chicago. The great predominance of cases of pediculosis pubis, in Chicago, which has been referred to by Dr. Greenough, may perhaps be explained by the fact that during the winter season when navigation is closed, many seaman congregate there. During the summer these men have been engaged along the coast and have indulged in all kinds of debauchery. They come under observation often in a very filthy condition, suffering with syphilis, pediculi and blenorrhagia.

DR. L. D. BULKLEY, of New York. I have heard no reference to a little lesion made by the pediculus corporis, to which attention has been directed by Dr. Tilbury FOX, and one which he considers of diagnostic value. This is a little hæmorrhagic spot resulting from the insertion of the proboscis of the pediculus into a follicle of the skin during the process of feeding. I should like to know if any of the members have put any trust in this as a diagnostic sign?

The President, DR. H. G. PIFFARD, of New York. A number of years ago I collected several pediculi vestimentorum and watched the process of feeding. I was able to verify the statement of Dr. Tilbury Fox. The proboscis of the pediculus corporis is not a cutting instrument, but is apparently inserted into a cutaneous follicle. After its removal, a minute droplet of blood will appear, which after a few hours becomes black. This sign is often of considerable value in diagnosis. In the treatment of this affection crude petroleum seems preferable to kerosene, which is sometimes used. I know of two cases in which the use of kerosene produced a violent dermatitis. Crude petroleum is less irritating to the skin, and is to be preferred in the treatment of pediculosis.

DR. J. C. WHITE, of Boston, read a paper entitled

AN INTRODUCTION TO THE STUDY OF THE INFLUENCE OF DIET IN THE CAUSATION AND TREATMENT OF SKIN DISEASES,

in which he spoke of the unfounded prejudices which exist in the public mind against certain harmless articles of food, and of the unproven opinions held by the profession upon the same subject. He pointed out the fallacious character of the evidence upon which many of these views were based, and described what seemed to him to be the proper methods of studying the subject. In conclusion, he enumerated the few substances which in his experience could be held as causative of disturbances of the skin when eaten.

DISCUSSION.

DR. J. N. HYDE, of Chicago. I can agree with the reader in regard to most of the articles of food mentioned. I should, however, put oatmeal in the list of foods which occasionally produce cutaneous trouble. I have seen one case in which an eruption on the face was always produced by the ingestion of this article even when used without the addition of anything else. I have in several cases thought that urticaria had been induced by the use of the Natal or seedless orange. Where urticaria follows the use of the grape, I think that it is principally due to the fact that the seeds and skin of the grape are also swallowed.

DR. E. B. BRONSON, of New York. While these articles of diet may have no specific effect on the production and course of skin affections, they may act in a reflex manner by causing disorders of the digestion. Many of them probably owe their effect to the fact that they are unaccustomed articles. Newly arrived emigrants frequently suffer from erythema and urticaria; this is especially true for emigrants from Ireland. This I have attributed to the radical change made in the diet, and have had good results by ordering the patient to return to his former diet, consisting largely of potatoes.

DR. E. WIGGLESWORTH, of Boston. I think that with oatmeal the effect depends largely on the size of the grain and the method of cooking. If not thoroughly softened, it may cause irritation of the mucous lining of the stomach and bowels, and induce urticaria, which as a result of scratching may pass into secondary eczema. It seems to me that salt air has some injurious effect in cases of eczema. My patients with eczema do better in the mountains than at the sea-shore. In the case of acne it is the reverse. Such patients are usually benefited by the sea-air.

DR. G. H. ROHÉ, of Baltimore. There seems to be no doubt that certain articles of diet, such as crabs and oysters, affect the skin more frequently than others, and yet I know of so articles so readily digested as oysters. The fact that they are unaccustomed articles of food may explain their effects to a certain extent; I have seen pruritus induced, as I supposed, by the use of buckwheat.

DR. P. G. UNNA, of Hamburg. In my private hospital I allow a liberal diet, and I rarely find it necessary to impose any restriction. I make it a point, by close questioning, to find out what articles seem to exert an unfavorable influence upon the condition of the patient, and then direct that they be avoided. I have seen urticaria produced by strawberries in cases where the berry has not been swallowed, but simply placed in the mouth.

DR. L. D. BULKLEY, of New York. I have more than one patient who cannot take raspberries without having urticaria. In some cases pineapples have a similar effect. Personally, I pay a good deal of at-

tention to the diet. Milk has not been referred to. I see many patients in whom injurious effects have followed the use of milk with the meals. If taken between meals it produces no injury. I have found that almost every case of acne is aggravated by soap taken with the food.

Dr. Le Grand N. Denslow, of St. Paul. I think that in this connection the quantity of food taken is of importance. Many people who do not lead active lives eat too much, and I have found it of advantage in certain cases to restrict the patient to one meal a day, allowing him, however, to eat all that he wants at this time. I would add to the injurious articles already mentioned, pork, veal, and anything fried.

(To be continued.)

[Special Report for the Journal.]

THE NINTH INTERNATIONAL MEDICAL CONGRESS.

GENERAL SESSIONS.[1]

FOURTH DAY. — THURSDAY, SEPTEMBER 8TH.

On the day of the meeting, the General Session was called to order by the President, who announced the Committee of seventeen to determine the place and time of the next session, the Committee organizing with Dr. Semmola, of Naples, as Chairman, and Dr. Assiky, of Bucharest, Secretary.

The Congress then adopted a resolution recommending the coöperative investigation of the results of yellow-fever inoculations as a preventive of that disease, in pursuance of the experiments of Dr. Domingo Freire, of Brazil.

The Congress then adopted a resolution commendatory of the proposed celebration, in 1892, of the discovery of America by Columbus.

Dr. Martin, of Berlin, was then called to the chair, and Dr. P. G. Unna, of Hamburg, then delivered, in German, an address upon

THE RELATIONS OF DERMATOLOGY TO GENERAL MEDICINE.

Dr. Unna's audience was not large, being confined mostly to Germans and those who could understand German. This paper embodied a plea for the more thorough study of skin diseases, and set forth with great force the importance of a wider spread of knowledge of the subject. He described with elaboration the difficulties which beset the path to a complete understanding of this subject, and the measures of success which had resulted from recent experimentation. He ended with a recommendation for the establishment of a central institute, where noted scientists may work together, and where all means and methods of study may be considered. This would, he believed, raise dermatology to the rank of one of our most important specialties in medicine, and would contribute largely to the progress of knowledge in all branches of medicine. He expressed the hope that the United States, always so liberal for the promotion of science, would be the first to develop this idea.

FIFTH DAY.— FRIDAY, SEPTEMBER 9TH.

A fair-sized audience gathered in the Opera House on Friday, the last working day of the Congress.

In accordance with the report of the Committee appointed the day before, Berlin and 1890 were selected as the place and time of the meeting of the next Congress. This was supposed to have been settled in Copenhagen three years ago, and by the same token, it may be assumed that St. Petersburgh will claim the prize in six years from now.

Dr. Davis then yielded the chair to Dr. J. D. Phillips, of London, and Dr. G. Fielding Blandford, of London, proceeded to deliver a paper upon

THE TREATMENT OF RECENT CASES OF INSANITY IN ASYLUMS AND PRIVATE HOUSES,

which had been originally prepared for one of the Sections. It was descriptive of various typical cases of mania or dementia met with in the practice of physicians, and suggested modes of treatment. He described many cases of mania that could be treated successfully at home, if the family was willing to defray the cost. But nine cases out of ten, he said, should be removed to a more suitable place. Dr. Blandford remarked that to harness a patient to a bedstead by his wrists and ankles was not treatment, though, unfortunately, even in this day, such practices were occasionally met with. He spoke of the reluctance that was felt by relatives of persons needing treatment to sending such to an asylum.

The non-asylum treatment of persons suffering from depression and melancholia, he said, has generally been tried before the services of the specialist are called in. Asylum treatment was necessary in most cases of suicidal patients, though, as shown by the report of the English commissioners of lunacy, confinement in an asylum did not always prevent suicide. Melancholia was the most tedious of all curable forms of insanity, because weeks and months were often required. So the question of expense came in in the cases of poor patients. To properly care for them at home would involve great expense. Then, to keep them in their old surroundings, was likely to aggravate the malady. The exaggerated egoism was a noticeable feature of such cases. At home, where they were the centre of attention, this was encouraged. In an asylum, where the patient became one of many, where he sat at the table with twenty or more others, and no one seemed to care whether he refused his food or not, it was different. The best treatment in many such cases, Dr. Blandford said, was what he called judicious neglect.

CLOSING SESSION.— SEPTEMBER 10TH.

A moderate audience assembled Saturday morning. The proceedings consisted of speeches by foreign delegates, who lauded the various committees of arrangement for the success of the Congress, and expressed their gratification at the hospitality received from the citizens of Washington, the President of the United States, and the Government officials. Surgeon-General Hamilton responded. He said the success of the Congress was due to the presence of the foreign doctors.

President Davis then made a few remarks, declaring this the greatest medical congress ever held, thanking the officers and delegates for their courtesy to the chair, and expressing his hope to meet many of the present delegates at the Berlin Congress.

Shortly after ten o'clock, President Davis declared the Congress adjourned *sine die*.

Most of the delegates then took the steamboat for Mount Vernon.

[1] Continued from page 236.

On the return from Mount Vernon, the foreign delegates were taken by special train to Niagara Falls, whence they were brought back Tuesday.

Wednesday evening there was no especial form of entertainment for the members of the Congress, outside of several private receptions. On Thursday evening occurred the great social event of the week, the "Reception by the Citizens of Washington," at the United States Pension Hall. Tickets to this were issued to the members of the Congress when they registered, but, on account of the goings-on at the gathering on Monday night, emphasized by the somewhat parallel scenes at the White House the next evening, all these tickets were cancelled, and new ones had to be obtained upon exhibition of each delegate's badge and certificate. The *Washington Post* thus speaks of Monday night's affair: "A humiliating experience was the presence of people whose appearance was not such as to give a flattering opinion to foreigners of American society customs. By some failure to comprehend the instructions given to those in immediate charge, gamins from the sidewalks, and laborers in their working-clothes, made their way in with those invited to greet and honor the visitors. A few creatures stalked about the great hall, wearing straw or slouch hats, and smoking cheap cigars, as at a country fair. The unwashed were few in number, in comparison with the better bred, but were all the more conspicuous."

The arrangements for this second gathering were far more successful, though it was a great bother to get the requisite new ticket. The foreigners were taken in by a side door, and, although there was a great crowd, there was plenty of room, no objectionable persons, and a few pretty dresses. The hall, itself a grand room, was handsomely decorated with bunting, and lit with both gas and electricity. More or less of those present were introduced to the officers of the Congress and some of the foreign guests, and the Marine Band played for the rest to promenade. A space at the lower end of the hall was screened off, and tables set around the three sides, behind which stood a corps of waiters. When the screens were removed, there was a mad rush for the tables, and, for the first hour, there was an animated struggle for provisions, men standing up to the tables six deep, the rear ranks vieing with the front in the endeavor to get or deposit dishes. American champagne flowed freely, and there was enough to feed all. The *menu* was very handsome, and made a beautiful souvenir.

SECTION OF GENERAL MEDICINE.[1]

WEDNESDAY, SEPTEMBER 7TH.

Wednesday afternoon's session attracted from fifty to sixty attendants.

The first paper was by DR. JOHN A. OUCHTERLONY, of Louisville, Ky., upon,

THE NATURAL HISTORY OF DISEASE.

Diseases, he said, are natural, though not normal, conditions. Nature is more powerful to cure than we admit in theory even, and much less in practice. Our knowledge of the natural history of disease is yet limited and we are prone to regard our treatment as potent. Our knowledge of familiar diseases has been completely altered in recent years, as, for example, the microbigenesis of phthisis and pneumonia. And yet, too, even in this Congress, the proved theories in regard to the pathogenesis of these diseases have been denied and derided. The cause of such wide diversity of opinion is to be found in our ignorance of the natural history of disease. Knowledge can be gained only by the concurrence of a large number of observers. Could we leave to themselves a large number of patients, we could judge of the natural history of their maladies. The plan is difficult of application, but the immense benefit should outweigh all objections. We treat hospital patients with drugs little, if at all, known. The nature that inflicts disease is likely to cure it. There are authentic instances of the spontaneous cure of even tuberculosis and cancer. The tendency to a spontaneous cure in acute cases is well known. The *vis medicatrix naturæ* is a living reality since under inert drugs recoveries so often occur. And recoveries take place from the same disease under exactly opposite treatment. Even in the hands of the ignorant and quacks patients often get well. In view of these facts, it would be perfectly justifiable to leave certain patients to themselves to observe the course of their maladies. Not all could be thus left; but even in private practice opportunities will occur, and it could well be done at hospitals. Especially should the teaching of the day be directed to encourage students to observe the natural history of disease.

The paper provoked a little discussion, and a remark by DR. SCOTT, that the man who keeps up to the times in therapeutics is a good physician, and that he himself had faith in medicine, evoked applause.

DR. T. D. CROTHERS, Secretary of the American Association for the Cure of Inebriety, then read a paper upon,

THE DISEASE OF INEBRIETY AND ITS TREATMENT.

Inebriety, he said, had been lately recognized as a disease, controlled by certain laws. Heredity, shocks, structural changes in nerve centers, unstable cerebral organization, certain diseases are all related causally. The craving for spirits is not the disease, but a symptom of it. The diseased nerve centres crave something in the shape of a narcotic, which craving, alcohol best supplies. The nervous degenerations may be central or not. The intervals between the paroxysms may be definite or variable. The phenomena of the paroxysms suggest the nerve storms of epileptics. The mental state is variable. Inebriety in America is becoming more marked in mental phenomena, more often concealed by the patient, more often ends in organic disease. It is on the increase in this country, while the moderate drinkers are decreasing. There is an ebb-and-flow movement in the amount of inebriety. Temperance agitators have a similar wave-like movement. The agitation for the cure of inebriety is increasing. Moral means, prohibition, educational methods have been tried and found ineffectual. Every inebriate sent to jail is more unfitted for temperate living. He suffers from cerebral anæmia, and needs better food and other influence than that of the jail. All the efforts of church, State and society are merely increasing the number of inebriates. And yet inebriety is a curable and preventable disease. Inebriates should be quarantined and treated like the insane, since they are insane. This could best be done in workhouse hospitals of different sorts for different classes of cases, whence those who had apparently re-

[1] Continued from page 239.

covered should be released on parole. Their practical success is demonstrated by the results of even such inebriate hospitals as there are, of whose cases twenty per cent. are cured.

A discussion followed, in which the relative merits of close confinement and religious influences as methods of treatment occupied a prominent place.

DR. W. R. CISNA, of Pennsylvania, produced a paper upon

TYPHOID FEVER.

After discussing the differential diagnosis, he considered the course of the disease, advised the expectant treatment, and laid stress upon the careful management of convalescents.

THURSDAY, SEPTEMBER 8TH.

An audience of forty or fifty people met Thursday morning and listened to a paper by DR. EPHRAIM CUTTER, of New York, upon

THE MORPHOLOGY OF RHEUMATIC BLOOD.

Dr. Cutter claimed to have found in the blood of rheumatic patients certain crystalline and other formations, illustrations of which, enlarged from microscopic views, were exhibited by a lantern.

DR. MARIANO SEMMOLA, of Naples, then read, in French, a paper upon the

PATHOLOGY OF ALBUMINURIA.

He further evolved his well-known views, as stated in previous publications, and further illustrated them by the results of recent laboratory and clinical observations made at Naples.

DR. R. SINGLETON SMITH, of Bristol, England, then presented a paper upon

INTER-PULMONARY INJECTIONS IN THE TREATMENT OF PHTHISIS,

taking the ground that they were of some value and should be tried when other means had failed. He also alluded to the Bergeon method of gaseous enemata, denying its usefulness.

Each of these papers were succeeded by a brief discussion of the point involved.

THURSDAY AFTERNOON.

The feature of Thursday afternoon, and, in fact, of the whole session of the Medical Section, was a paper upon

DIABETES,

by DR. F. W. PAVY, of London, Eng., the well-known authority upon dietetics, which attracted an audience of a hundred and fifty, and was greeted by warm applause at its close. After an apology for the necessary incompleteness of his extempore address, Dr. Pavy went on to say that diabetes has always been considered an inscrutable disease, but that its nature may be expressed in precise terms, without entering upon theoretical questions, as a faulty disposal or assimilation of certain elements of food. Food may be divided into three classes: nitrogenous, fatty, and the carbohydrates; and it is the latter group, without distinction between its members, that is the subject of faulty disposal in diabetes. In health an ingested carbohydrate is lost sight of, and we may assume it is transformed for utilization by the economy. In diabetes it is eliminated as sugar and in proportion to the carbohydrate ingested. The sugar reaches the general circulation in a way it ought not to. In health there is but a faint trace in the general circulation, so that the ingested carbohydrate is stopped on its way, while in diabetes it exists in large quantities in the general circulation, whence it is removed by the kidneys. And the proportion in the urine is the proportion in the blood. Why it gets into the blood is the essential question. The liver is the a-similative organ and stays the carbohydrate in its progress. People who eat much of the carbohydrates grow fat, as do the lower animals when fed on them. So that the liver seems to be really rather a steatogenetic than a glycogenetic organ. The carbohydrate, changed first into glycogen and then into fat, passes away from oxidation rather than towards it. In diabetes there goes on a faulty chemical process in the liver and a wrong condition of the blood of the portal vein. The liver has a comparatively small supply of arterial blood, but a large supply of venous blood. When it does not have good venous blood, there is sugar in the urine, as shown by injecting arterial blood into the portal vein, or when the blood of the system is over-oxidized as shown by the respiration of oxygen or carrying on respiration to excess. To produce a similar condition, we need only a vaso-motor paralysis of the vessels of the chylopoietic viscera. If the arteries of the abdominal viscera are dilated and allow the passage of more blood than can be de-arterialized, then the portal vein gets imperfect venous blood, and this permits the carbohydrates, charged with glycogen, to pass through the liver into the general circulation. The vaso-motor paralysis may extend beyond the chylopoietic viscera. For example, the worst forms of diabetes in the speaker's practice were those accompanied by an intense redness of the mouth, tongue, etc. It is well known that puncture of the floor of the fourth ventricle causes glycosuria in the same way, as does also vision of the sympathetic. In the speaker's opinion, diabetes was a disease of a neurotic nature, as he had found that nerve conditions, as well as food, influenced the patient, and nerve conditions might affect the chylopoietic viscera.

Difference of opinion as to diagnosis, depends sometimes on the relation of glycosuria to diet, and sometimes upon error in the test. The best test is with copper, but Fehling's solution is liable to get bad from keeping, and the potash fixes the stopper in the bottle. Its ingredients (copper, Rochelle salt, and potash), can be made, however, in an anhydrous form in a pellet and used just like the solution. In a well-stoppered bottle they keep forever, and if moisture does affect them, they get so bad and black as to be evidently useless. But we are still in the dark unless we know the amount of sugar. One needs two specimens, one of the urine passed on retiring at night, and one on rising in the morning. These will enable us to detect errors of diet, even the meal at which carbohydrates were taken, and sometimes even call attention to unconscious mistakes in diet. For example, blanc mange, properly made with gelatine and cream, has caused glycosuria by being made of corn starch. The quantitative estimation needs to be easily and accurately done, and the ordinary means, by Fehling's solution, can be greatly improved upon by making an ammoniated solution, which permits the reduction but not the precipitation of the copper. Therefore, the exact moment when the blue cupric solution is decolorized can be plainly seen, not being obscured, as in

the ordinary method, by the precipitated suboxide. Sometimes albuminuria is present. At first it may be considerable, but under the dietetic treatment, usually disappears. This suggests a test for albumen. The most convenient one consists of two pellets, one of citric acid and the other of ferrocyanide of sodium. Dissolve the citric acid in the suspected liquid and there may be a precipitate (usually uric acid), which disappears on dilution. Then dissolve the ferrocyanide pellet, and there is a precipitate if albumen is present. Nothing else is needed; the test is very delicate, and the precipitate is caused by nothing else but albumen.

There are many grades of the disease, varying in intensity. A healthy person, fasting, may consume an excess of carbohydrates and then have glycosuria. The first step in the diabetic process occurs when the assimilative powers are a little below par; it may reach a state where sugar is excreted without the ingestion of any food, sugar being formed from the body itself. The severest cases are in the young. The older the patient, the better the prognosis. No disease of the young is graver. The speaker never knew a young diabetic recover. The ordinary duration in a young person is two years. In the middle-aged or the old, it is their own fault if they go wrong. It is common from forty to sixty, which was the age in fifty-five per cent. of the speaker's 1360 cases. It may go on for some time unrecognized, which is shown by the presence on cast-off clothing of the white spots diabetic urine leaves. It runs in families in a marked manner. The speaker instanced a case where four out of five children had it, the mother and grandmother having died with it. In elderly diabetic patients there are often pains in the legs, more or less ataxia, hyperæsthesia, and paræsthesia of the skin, tender flesh, aching bones,— apparently a peripheral neuritis.

In the young, the progress of the disease can merely be stayed. There is no cure. There may be under treatment great temporary improvement, but the disease is progressive nevertheless. The sugar, if for awhile absent, reappears and goes on increasing. The thirst and polyuria may even yet be checked, but the disease goes on, something throws the patient off his balance, and he dies with diabetic coma. It is quite different, however, after the middle period of life. Here there are two points to be looked to — not to feed the disease, and to convert the wrong assimilative action into the right one. The regulation of the diet is an absolute necessity. This is easy enough in some ways, but hard in others. Any animal food will do, meat, fish, game, eggs, butter, cheese, milk sparingly. As to bread,— brown bread, usually has plenty of starch; gluten bread may be palatable, but is apt to be largely starch. Probably bread made from almonds which contain only seven to eight per cent. of carbohydrates and fifty per cent. of fat, is the best. To alter the assimilative functions, nothing seems so good as some form of opium, morphia or codeia. The speaker used them and believed them to have a restraining influence upon the disease. After a few months of freedom from glycosuria, the speaker allowed patients two ounces of bread per diem. If this were well borne, after a while he increased it to three ounces, then to four and one-half, then to six, and then, after a longer interval, they often returned to ordinary diet, and had no glycosuria. Sometimes, however, with the restoration of bread, the glycosuria returned. It is to be remembered that the diabetic patient has an aptitude for any disease. If his condition is neglected, life is gradually sapped.

In reply to questions, Dr. Pavy said that Jews had a peculiar predisposition to diabetes. It was more common among them, and more amenable to treatment. He was not a believer in acetonæmia. Bromide of arsenic had no value except while it was being given. Ten or twelve months was the age of the youngest diabetic he had ever seen.

The next paper upon

THE ÆTIOLOGY OF PHTHISIS

by DR. C. D. F. PHILLIPS, of Edinburgh, was read by DR. STOCKMANN, of Edinburgh.

From the writer's experiments with a substance extracted from the sputa of phthiscal patients, he had been led to believe that the disease was due primarily to the bacillus tuberculosis, which produced a ptomaine, and that this caused the sweating, fever, and other symptoms of phthisis. In his experiments this appeared to be antagonized by atropine, which explained the therapeutic value of the latter in phthisis.

This was followed by a paper entitled

SOME CONSIDERATIONS UPON THE PATHOGENESIS OF DISEASES OF WOMEN,

by DR. W. B. NEFTEL, of New York.

Experiments by the author upon animals, suggested that compression of the chest might induce death by arterial anæmia and venous stasis, but not by tuberculosis.

FRIDAY, SEPTEMBER 9TH.

Friday morning a moderate sized audience was present.

DR. GEORGE E. STUBBS, of Philadelphia, presented a paper upon

THE RATIONAL TREATMENT OF DISEASES OF THE RESPIRATORY APPARATUS,

in which, after a consideration of the anatomical structure of the lungs, he went on to consider phthisis more in detail, advising the treatment by counter-irritation, tonics, expectorants, cod-liver oil, or cream, and atomized inhalations.

DR. EGE, of Reading, Penn., in the discussion detailed his method of treating pulmonary tuberculosis, which consists in the deep inhalation of an atomized solution consisting of the white of egg and water, allowed to stand for some days. The microbes developed in the egg solution were supposed in some way to influence the bacillus tuberculosis. Under its use the cough grows looser, and the symptoms of phthisis decline. The bacilli of tubercle at first increase and then decrease to *nil*, when a cure is effected. The solution may be called an impure cultivation of the bacterium termo.

The next paper was by SIR JAMES GRANT, of Ottawa, Canada, upon

DIPHTHERIA.

He had seen, in Canada, two classes of this disease, one simple, and the other so malignant that the internal carotid artery even sloughed, and the patient died of hæmorrhage. He considered it a blood-disease, and that the essential thing in treatment was to determine the poison from the throat. To do this, he gave

daily mustard-baths, and, under this method, had had sixty-three recover out of sixty-five, one dying from tracheal diphtheria, and one from cardiac paralysis. He drew especial attention to the danger from a weak heart in the later stages.

FRIDAY AFTERNOON.

The closing session of the Medical Section was held Friday afternoon, with a good attendance. The Section adopted the report of a Committee appointed to examine into Keller's statistics on vaccination in Hungary, denying their claim to repute, and endorsing Korosi's position in regard to them.

In default of expected material, Dr. Abram Arnold, President of the Section, came to the rescue with a paper upon

FATTY AND DILATED HEART.

After a consideration of the pathology and symptoms of weak heart, he passed on to its treatment. Digitalis answered well for a while, and, when that failed, strychnine, in his hands, had proved of great value in large doses, even up to one-tenth of a grain, given three times daily. He believed the new treatment of exercise was founded on rational principles.

Dr. G. E. Fell, of Buffalo, N. Y., then read the final paper, upon

FORCED ARTIFICIAL RESPIRATION IN OPIUM-POISONING,

founded upon a recent case in his practice, where, by tracheotomy and forced respiration by means of the machines used in physiological laboratories for artificial respiration in narcotized animals, he had resuscitated a man apparently in *articulo mortis*, after all other means had been tried. The patient had taken from fifteen to twenty grains of morphine, the respirations had come down to one per minute, the pulse could just be detected, cyanosis had appeared, and the pupils were widely dilated.

This was succeeded by discussion and final adjournment.

SECTION ON GENERAL SURGERY.[1]

TUESDAY, SECOND DAY — MORNING SESSION.

The first paper read was entitled

A NEW FORM OF ABDOMINAL SUPPORTER,

by Dr. Felix Debaker, of Roubaux, France.

This supporter differs from most others in being thickly padded. It receives its support from behind and encircles the abdomen, grasping it as a hand. It sustains the intestines which tend to bear down upon the uterus. It gives relief to the lateral ligaments which have been stretched during pregnancy. It supports the muscle and skin over-distended during pregnancy.

THREE HUNDRED AND EIGHTY-FOUR LAPAROTOMIES FOR VARIOUS DISEASES,

by Dr. John Homans, of Boston.

The author confined himself wholly to his own experience. Of the 384 laparotomies, 282 were ovariotomies; 27 removal of uterine tumors; 19 simple exploratory laparotomies; 15 laparotomy and stitching the ovarian cyst to the skin; 5 removal of uterine appendages, for fibro-myoma; 5 removal of uterine appendages, for nervous diseases; 1 pyosalpinx; 1 tubo-ovarian; 1 abdominal abscess; 2 removal of immense lipoma; 4 intestinal obstruction; 3 renal tumor; 1 perityphilitic abscess.

The general method of operating is as follows. The sponges are prepared by soaking in 1-1000 corrosive-sublimate solution. They are then wrung out dry by an ordinary wringing machine. They are then kept in a 1-20 carbolic solution. The carbolic spray is always used, although it was considered unnecessary. An electric light is always kept in readiness.

Of the first five unantiseptic operations all the patients died. Of the antiseptic operations 248 recovered, and 34 have died. The vitality or viability of the patient has much to do with the result of the operation. The usual causes of death have been peritonitis or septicæmia. He was sceptical about the occurrence of mechanical intestinal obstruction, except as the intestines are paralyzed by peritonitis. Two cases in which the bladder was wounded during ovariotomy, recovered and are living, two and six years respectively after the operation. In both cases the opening in the bladder was closed with silk sutures. Of the recoveries, nine patients died of abdominal cancer a few months or years after recovery, and thirty have ventral hernia. Fifteen children have been born to eleven women out of about two hundred heard from. The sexes do not correspond to the ovary remaining.

The usual length of the incision is about two inches. The stump is always tied, burned, and dropped back. Silk sutures are used, and care is taken to include all the abdominal parietes, particularly the transversalis fascia. Drainage was used in fifteen cases. The greatest number of consecutive recoveries after ovariotomy has been thirty-eight. The author had never seen a suppurating ovarian cyst but once, and in that case the cyst had been tapped. There are cysts which contain fat and sebaceous matter, and to the naked eye their contents look exactly like laudable pus, and can only be distinguished from it by microscopical examination. There were two cases of swelling of the parotid gland after ovariotomy. Both recovered quickly, and the speaker did not regard enlargement of the parotid during convalescence as of especial importance.

The cases of removal of uterine fibroid tumors number twenty-seven, with seventeen recoveries. The later cases have nearly all recovered. The operation is never done unless the patient is in danger of her life from hæmorrhage, mechanical pressure, or exhaustion, or she suffers severe pain.

In the cases of ovarian cysts, uncomplicated except by adhesion, where the tumor could not be removed, and in which the cyst was stitched to the abdominal wall, numbering nine, recovery has followed. The author had but one case of collection of pus in the abdominal cavity, which was treated successfully by laparotomy and drainage.

Of salpingitis and abscess of the ovary due to gonorrhœa, there had been one case. This was treated by removal of both tubes and one ovary, the other ovary being so adherent that it could not be removed. The patient recovered. Of removal of large intra-abdominal fatty tumors, there were two cases, both ending fatally. The speaker had one case of operation for closure of Meckel's diverticulum in an infant of five months of age, resulting in complete cure. In one case of intestinal obstruction caused by Meckel's diverticulum occurring in a young man twenty-one years

[1] Continued from page 241.

of age, the case resulted fatally. One case of cure of tubercular peritonitis and dropsy, by laparotomy was reported. The patient is now fat and healthy, three years after operation.

Three cases of removal of the kidney for sarcoma, caries and abscess were operated on with fatal result. There were five cases of lumbar colotomy, or pubic colotomy, three of which were successful. The author had removed a fibroid tumor in the abdominal fascia and peritoneum of the right lumbar region by laparotomy. The patient is now in good health, four years after operation.

A number of cases of special interest were briefly reported and an exhaustive table of all the cases operated on was given.

The following résumé was given.

282 Ovariotomies, ...	248 recoveries,	34 deaths.
27 Hysterectomies, ...	17 "	10 "
32 Partial removals of uterine and ovarian tumors, ...	10 "	22 "
19 Exploratory operations, . .	16 "	3 "
10 Removals of uterine appendages,	9 "	1 "
14 Miscellaneous laparotomies, .	5 "	9 "
348 Laparotomies.	305 "	79 "

AN IMPORTANT POINT CONNECTED WITH ABDOMINAL SURGERY,

by DR. ADDINELL HEWSON, of Philadelphia.

The point referred to was in connection with the coaptation of the wound after laparotomy. The diminution of the number of ligatures and the lessening of their irritating properties is of great importance. The abandonment of sutures was recommended, the wound being kept in apposition by means of gauze secured on each side by book-binders glue. The glue is not applied nearer than one-half inch from the wound. This dries as quickly as collodion, dries on a moist surface, and holds securely. Gauze so secured, will support twenty pounds to the square inch. It is not disturbed by motion or distension.

WHEN IS COLOTOMY JUSTIFIABLE?

by DR. J. M. MATHEWS, of Louisville, Ky.

The following conclusions were presented:

(1) Colotomy is not justifiable in cases of cancer of the rectum.

(2) In stricture or obstruction of the rectum from whatever cause, within three and one-half inches of the sphincter, colotomy should not be done.

(3) The operation is not warranted in cases of ulceration of the rectum unless of specific origin and accompanied with stricture beyond the reach of the finger.

(5) Colotomy should not be performed for the presence of a tumor or aneurism, causing pressure on the bowel.

(5) In cases of congenital occlusion of the rectum, the operation is not to be recommended.

(6) In cases where the operation is looked upon as a *dernier ressort*, colotomy should not be done save for total obstruction, of benign or specific origin, located farther than three and one-half inches above the sphincter.

Where the rectum or sigmoid flexure is closed by a stricture of benign or specific origin, colotomy is indicated.

The reasons for advising against colotomy in the cases given above were first, that the operation does not prolong life; second, admitting that life could be prolonged, the operation is not advisable; third, instead of prolonging life surgical interference shortens life, and fourth, the pain is not materially lessened by the operation. Where the disease is located within three and one-half inches of the sphincter, it may be treated by division. In other cases rectotomy was recommended.

The discussion on the papers on laparotomy was postponed until the afternoon session, and it was decided to at once proceed with the discussion of Dr. Mathews' paper.

DISCUSSION.

DR. DAWSON, of Cincinnati. I agree that colotomy is a fearful resort. I have never performed it with any satisfaction to myself and but little to my patients. There are, however, cases in which it seems to be indicated. I have now a patient, a young man of seventeen years, with an immense cancerous mass in the rectum almost beyond the reach of the finger and narrowing the calibre of the bowel to one-half inch. There is, however, not the slightest sign of cachexia. The growth is accompanied by extreme pain. I have almost decided to open the abdomen, and if possible remove the mass with a portion of the gut. This operation has been done in Europe, but it is not old enough to enable us to judge of the results to be obtained. In syphilitic cases, where there is stricture, the stricture disappears under anti-syphilitic treatment.

DR. J. M. QUIMBY, of Jersey City. I agree with Dr. Mathews in the views that he has expressed. I have performed operations similar to that suggested by Dr. Dawson, but the result was not satisfactory. Unless there is total stricture, the operation is hardly justifiable.

DR. SAMUEL BENTON, of London. I understood the author to say that colotomy is not to be recommended for total obstruction due to cancer of the rectum. My practice is, if I can get beyond the cancer, to do extirpation. If the growth is so high that I cannot remove the whole of it, I perform colotomy. I would recommend colotomy in these cases of cancer of the rectum. In the cases that I have done, life has been prolonged about fifteen months after colotomy. The last case lived about eighteen months. There was complete obstruction, and, if operation had not been performed, the patient would have died in two weeks. It is my experience that the straining and bearing down at stool is relieved by colotomy. The growth, to a certain extent, remains at a standstill, and a considerable amount of the pain is relieved. After rectotomy, the stricture quickly returns. I treat benign tumors by electrolysis. This quickly relieves the stricture. The treatment is safe, and can be continued while the patient remains at his ordinary work. I do not say that the stricture does not return, but it can be kept down by a repetition of the electrolysis, or by dilatation practised by the patient.

DR. J. W. C. O'NEIL, of Gettysburg. The proper course to be pursued in the case referred to by Dr. Dawson would be to put the patient under chloroform, inject the mass with carbolic acid, and scrape it out. This will afford relief.

DR. J. W. HAMILTON, of Columbus. I would utter a word of warning against the use of carbolic acid in the treatment of diseases of the rectum. The use of this agent is fraught with danger. Where there is

obstruction, due to cancer of the rectum, colotomy should be performed.

Dr. E. M. Moore, of Rochester. With reference to the case of Dr. Dawson, I would say that it is extremely rare to have cancer in a person only seventeen years of age. At that age, sarcoma is very common. This is not accompanied by the cancerous cachexia, and every surgical operation for sarcoma is a failure. I would strongly object to the operation proposed, and would recommend colotomy.

Dr. W. N. Hingston, of Montreal. The operation of colotomy should be performed where there is obstruction. It also relieves pain. When the whole of the mass can be gotten away, rectotomy should be performed.

Dr. J. W. C. O'Neil, of Gettysburg. I have used carbolic acid for ten or fifteen years, and, as a general rule, have found it of value.

Dr. Mathews. I would merely say that carbolic acid is a hazardous remedy, and has caused much damage, and has led to hundreds of deaths.

Adjourned.

AFTERNOON SESSION.

DISCUSSION OF PAPERS ON ABDOMINAL SURGERY.

Dr. W. N. Hingston, of Montreal. It has been said that hæmorrhage and shock are misleading, and I agree with this. Fæcal discharge clearly indicates operation. The rule to operate when in doubt is a good one, for the exploratory incision cannot add to the risk.

With reference to the length of time required for operation, while it is desirable to operate with all possible speed, all hurry should be avoided. Time is not of such moment as is generally supposed. It has been asserted that gangrene was not the result of interference with the arterial supply. This is contrary to all of my previous ideas, but I am not in a position to deny it. Dr. Senn's paper is, without exception, one of the ablest papers I have ever listened to.

Dr. Homans speaks of having had ventral hernia in ten per cent. of his cases. This strikes me as large, and I would ask how he closes the abdominal wall, whether he takes only the skin and peritoneum, or includes everything.

I would direct particularly attention to the Doctor's statement that he has performed five operations of removal of the ovaries for nervous disease, with only one success. This is quite different from the reports usually made. The removal of normal ovaries seems to be epidemic in certain places. I have never removed an ovary weighing less than fifteen pounds. The immunity that attends abdominal section has made these operations very, very frequent.

Dr. J. B. Murphy, of Chicago. In the three cases which I have had there has been no shock, and no appearance of fæcal matter in the wound, although, in one case, there were eleven wounds. While, in the majority of cases, the median incision is the best, there are cases in which enlargement of the wound is to be preferred. The operation should be done early, for, after severe peritonitis has set in, the operation will be of little service. If there is penetration, an exploratory operation will not add to the danger; and, if the intestine is wounded, death is certain.

Dr. W. F. Beck, of Davenport. I would report a case in which I opened the abdomen of a man apparently suffering from intestinal obstruction. I found a portion of the ilium strangulated under an adherent vermiform appendix. I tied the appendix in two places, and divided it. The patient made a complete recovery. There were no antiseptic precautions adopted in this case. With an experience of seventy-eight cases of ovariotomy, it seems to me that our results are improving, and, as we devote ourselves more to aseptic surgery, and less to antiseptic surgery, I think that our results will be better.

In the treatment of the pedicle, I do not use ligature, but rely on the actual cautery, not having the iron too hot, and applying it to the pedicle, held between clamps. After the application, the pedicle is allowed to remain five minutes undisturbed, and the clamp is then carefully removed. There is no fear of hæmorrhage after this procedure.

Dr. S. C. Gordon, of Portland. I have seen but three cases of ventral hernia in eighty operations. These were due, I think, to the use of silver wire in closing the abdominal wound. It is difficult to twist silver wire so as not to strangulate the tissues. If the part is strangulated, absorption is likely to occur. I now always use silk and include the transversalis fascia and linea alba. In hysterectomy I have treated the pedicle in an intra-peritoneal way and 90 per cent. of the cases have recovered.

In regard to cases of so-called normal ovariotomy, I have seen cases cured by operation in which all other measures had failed. I have done Tait's operation in thirty-three cases with three deaths. Twenty-five of these patients consider themselves well. Four or five have not been benefited.

Dr. Coudin, of Rock Island, Ill. Dr. Senn states that overdistension of the bowel causes longitudinal rupture of the peritoneum. Some years ago I suffered intussusception in my own person, the invaginated portion reaching almost to the anus. After other measures had been resorted to, I injected the bowel through a long, rubber tube. There was a sudden report, the bowel returned to its position, and the water entered. In my case the injection evidently passed through the ileo-cæcal valve.

Dr. Kreicher, of Springfield, Ill. I would add to the cases of Dr. Parkes, a successful case of laparotomy for gun-shot wound of the intestine in the practice of Dr. David Prince, of Jacksonville. I have seen four cases of intestinal obstruction. The first was a case of acute obstruction. I saw the case one week after the onset of the symptoms, and proceeded to the operation. The intestine was in such a condition that the operation was abandoned and the patient died. In the second case, there was in connection with the obstruction extensive miliary tuberculosis of the peritoneum, and it was impossible to proceed with the operation. The third case was one of strangulated hernia, although there was no external evidence of the condition. The patient died eighteen hours after operation. The fourth case was one of one week's duration. Operation was recommended but not accepted. It is my opinion that cases of intestinal obstruction which do not yield to ordinary medication, injections and massage, should be submitted to exploratory incision, and the operation should not be delayed.

Dr. Satterthwaite, of Louisville, Ky. The first thing to determine is whether or not the abdominal cavity has been opened. This can only be done by careful exploration. There may be a valvular

opening which will not permit a probe to pass. If penetration is determined, the wound should be enlarged and the opening in the intestine closed by sutures, including only the peritoneal and muscular layers. If you wait for shock and the passage of fæces the case will usually die.

DR. LINK, of Terre Haute. Gun-shot wounds of the intestine, even if not operated on, are not necessarily fatal. The presence of food in the peritoneal cavity is not of necessity fatal. I believe that many cases of pistol-shot wounds of the abdomen with perforation of the intestine, recover without operation. A probe should not be introduced into the opening until we are ready to proceed with the operation.

DR. PALMER, of Jonesville, Wis. In reference to the passage of fluids injected into the bowel through the ileo-cæcal valve, I would say that I have performed a number of experiments on dogs, producing invagination artificially. Rectal injections were then resorted to with the effect of relieving the invagination in the majority of cases. The same procedure has been resorted to in the human subject with satisfactory results in two cases. If we can relieve intussusception by fluid or gaseous injections we do away with the need for the knife, and if they fail, the knife can be used afterwards.

DR. A. C. BURNEYS, of St. Louis. In connection with Dr. Senn's recommendation of intestinal anastomosis I would mention a suggestion which I made in 1883. In order to form a communication, say between the stomach and intestines, an elastic ligature may be passed into the stomach and brought out a short distance from the point of entrance. The needle with the ligature is then passed into the bowel, brought out, and the ends tied together. Adhesion takes place and the ligature cuts through in twenty-four to thirty-six hours. This will do where you can wait, but when a communication has to be established at once, Dr. Senn's operation is eminently useful.

DR. GILMAN, of Lowell. I have treated three cases of pistol-shot wound of the abdomen without operation. In the first case there was a wound of the intestine with death from peritonitis. The second case had a wound of the stomach and recovered without a bad symptom. The third case resulted fatally from peritonitis.

DR. T. G. RICHARDSON, of New Orleans. I recently saw a case in which there was undoubted wound of the intestine, and the patient recovered without operation. The records of the Charity Hospital show that more than one-half of the cases of penetrating abdominal wounds in negroes, recover, while more than one-half of the cases in the white race die.

DR. RIDGE, of Kansas City. I have seen several knife wounds penetrating the stomach in which recovery followed without operation, and I think that I have seen as much damage from the operation as from waiting.

DR. DAWSON, of Cincinnati. I have made several experiments on the cadaver with reference to the possibility of passing fluids from below through the ileo-cæcal valve. In twelve cases, I found it impossible to pass fluid through. In one case fluid appeared in the mouth. Examination showed the valve to be imperfect. In the normal condition it will not allow fluid to pass.

DR. PARKES, of Chicago. The results of my experiments on animals shows the necessity of bringing large surfaces of peritoneum in contact. With regard to Dr. Senn's suggestion for the treatment of multiple wounds of the intestine, I think that it is not necessary, for the plan of treatment by the continuous suture is sufficiently rapid and answers the purpose.

THREE CASES OF LAPARO-NEPHROTOMY,

by DONALD MACLAIN, of Detroit.

CASE I. Mrs. A., aged twenty-five years, presented herself with what had been diagnosed as an ovarian tumor. There was a cystic abdominal tumor about the size of the uterus at the seventh or eighth month of pregnancy. There was no history of renal trouble and no evidence that the tumor was connected with the kidney. The patient insisted that it had begun to grow from below. The operation was done with the expectation of removing an ovarian tumor. The left ovary was found enlarged to the size of a goose-egg, and was removed. The large tumor was found to arise from the kidney and it was removed. The patient did well for a time, but suppuration with the formation of a fæcal fistula occurred, but the patient finally made a perfect recovery.

CASE II. Mrs. T., aged forty years, presented herself, with a tumor of the left side of the abdomen, which had been discovered six years previously. The enlargement had gradually increased. The tumor, when first seen, was too high for the ovary and too low for the spleen. The urine was normal. A diagnosis of tumor of the left kidney was made. It was decided to adopt the trans-peritoneal method of operating. A large cyst of the kidney was found. During removal it ruptured, with the escape of a material like soft soap. The posterior layer of the peritoneum was brought together with sutures. The case did well until the eleventh day when the temperature went up until it reached 104°. Examination showed fluctuation in the lumbar region. An opening was made with the escape of a large quantity of pus. Symptoms of collapse followed this operation, but these were overcome and the patient made a gradual recovery.

CASE III. A female infant, twenty-two months old. The family history was good. There was a tumor in the right hypochondriac region. This was movable and free from tenderness and pain. Tumor of the kidney was diagnosed and removal recommended. The incision was made just external to the rectus muscle. No difficulty was experienced and the operation was completed in seven minutes. The posterior layer of the peritoneum was closed with catgut sutures. For several days the case progressed favorably but the temperature remained high. On the fifth day a careful examination was made to determine the cause of the elevated temperature. During the examination the child coughed and the abdominal incision gave way, allowing the intestines to escape. These were replaced and a search failed to show the source of the trouble. The wound was reunited. The temperature continued high and the child died on the ninth day. At the autopsy the posterior layer of peritoneum was found united and in the space occupied by the tumor a small collection of pus was found surrounding the ligature on the pedicle of the tumor.

The speaker said that while the lumbar operation might be the safer, there were cases in which the trans-peritoneal operation was preferable. These cases point to the necessity of securing efficient drainage, although antiseptic precautions were adopted.

TUMOR OF THE HEAD, PROBABLY INTRA-CRANIAL.

A patient with a tumor of the head was presented to the Section and was referred to a committee for examination. The committee consisted of Drs. Moore, Dawson, and Brosseau. It reported that there was a large tumor of the head, five inches in diameter, occupying the tempero-parietal region. This occurred in a man thirty-five years of age, and appeared twenty months ago. There was some headache. There was some blindness, greater on the right side. There was deafness on the left side. The tumor was raised one inch above the surface. The committee believed that the growth was intra-cranial, causing expansion and partial absorption of the bones. While operation would hardly be successful, still, as the case must progress to a fatal termination, it would be proper to remove a portion of the skull, and if the growth was outside of the dura mater, there would be a reasonable prospect of success.

The Section then adjourned.

THIRD DAY, WEDNESDAY, SEPTEMBER 7th.

LAPARO-NEPHRECTOMY.

The meeting being called to order at eleven A.M., the discussion of Dr. Maclain's paper on Laparo-nephrotomy was taken up. The discussion was opened by Dr. Herff, of San Antonio, Texas, who said:

I quite agree with Dr. Maclain that in suitable cases laparo-nephrotomy is the proper operation. Some years ago I had a case of a young woman who was newly married, and when about two months pregnant she discovered a tumor on the right side, which was nearly as large as a child's head. She had no pain and except that she had this tumor, she was in good health. The tumor, however, annoyed her very much, and she insisted on an operation being done. I therefore opened the abdomen in the median line and removed the tumor.

The remarkable thing about the case was that the tumor, which I had thought an ovarian one, proved to be the kidney and supra-renal capsule. From the lower end of the tumor the lower part of the kidney was hanging, while the upper part consisted of the supra-renal capsule enormously enlarged and sections of which presented under the microscope the appearance of the long cells of myoma.

The patient made a good recovery, and two years after the performance of the operation, she was in perfect health.

This, while a case of removal of the kidney, was also a removal of the supra-renal capsule. This made the case more remarkable to me because I have never read of its removal for disease.

Dr. Dawson said, About these cases I wished only to thank Dr. Maclain for his kindness in bringing them before the Section. It is very interesting to look back a few years and see the advance in surgery that has taken place.

Dr. Hughes said, I had precisely the same number of cases of kidney disease as Dr. Maclain, and I perfectly agree with him in everything save one, and that is the seat of operation. He seems to prefer the abdominal incision, while in all cases where it is practicable I would give the preference to the side, between the rib and crest of the ileum. My first case I operated on by means of the abdominal incision the only way that I could do, as the tumor was so large a one that it could not have been brought through the opening between the ribs and the crest of the ileum. The second case was only a tumor about the size of the fist, and I operated in the space between the ribs and anterior crest of the ileum. I also operated on the third case by incising the lumbar region, and from these last cases I got the best results and also avoided opening the peritoneum.

Dr. Edward Owen, of London, remarked: There are at least three factors which must influence the choice of the operation in each case; first, if there were doubts as to the exact nature of the tumor, the anterior operation would be chosen, and second, if the tumor were very large, the anterior incision must be chosen. Lastly, there was the line of practice of the individual surgeon. The gynæcological operator would naturally prefer the trans-peritoneal incision, even for a small tumor, because that is, to a certain extent, his own province, while the general surgeon would choose the space between the last rib and the iliac crest, because, for some reasons rather indefined, he does not care to touch the peritoneum if he can avoid it. In a case of diseased kidney which I removed successfully, I made the incision through the luna semilunaris.

Dr. Harden remarked: I had a case somewhat similar to one which has been related here. In my case, I made the anterior section, but did not remove the tumor, on account of an enormous flow of blood, which would have become so alarming if we had attempted to separate the tumor from its connections, that I feared the patient would die, so all further operation was stopped. The tumor was shown after the death of the patient to be a kind of fibro-cystic tumor of the kidney.

Dr. Lange, of New York, said: In a large number of these cases of tumor of the kidney where there is fluctuation, they are cases of pyo-nephrosis of usually very large size. I have operated several times for the removal of the kidney, and performed both the anterior and posterior operations. In the small tumors, and in some of the larger ones, I prefer to make a small lumbar incision to empty the contents of the tumor out as far as possible, and then wait until the remainder of the tumor lessens in size, which it will be very apt to do, so that it can be gotten out through even a very small hole or incision.

Sometimes, in renal calculi, I have performed laparotomy, or rather, the operation in the lumbar region, and then, after making this incision by placing these patients in bed, lying on their stomachs on a pillow, the kidney would float up when the wound was made, and could easily be gotten up, and the calculus removed.

Dr. Maclain, in closing the discussion, said: I have been misunderstood in the discussion because I choose the operations in the front of the belly, instead of the lumbar incision. There were very good reasons in each of the cases I have had why I should choose the anterior operation; they were all too large for the lumbar incision.

Dr. M. H. Richardson, of Boston, next read a paper entitled

GASTROTOMY FOR FOREIGN BODIES IN THE ŒSOPHAGUS,

in which he said that this operation was intended only for the removal of foreign bodies in the œsopha-

which had passed so far down the œsophagus as to be lodged near the cardiac orifice. In regard to the length of the incision, it was not fixed. It might be only a very short one, or it might be made large enough to put the hand inside the stomach, so as to reach up into the œsophagus, if that should be necessary in order to extract the foreign body. The incision through the skin should be made over the cardiac end of the stomach, or might be made in the median line, and the incision through the walls of the stomach must be made in the cardiac end of the stomach. All the caution necessary in making this was to get the incision made without wounding the convexity of the lesser curvature of the stomach, and, in order to avoid this, the better way was to put the lesser curvature on the stretch. After the opening into the stomach was made, instruments might be introduced for the dislodgement of the foreign body, or, if they were insufficient, the fingers and hand might be passed in, which would enable one to relieve the œsophagus of its burden. As to the scope of the operation, while it was chiefly applicable to the removal of foreign bodies, it might be useful in other ways, as its capabilities were considerable, as was demonstrated by his experiments on the cadaver. He concluded that if the foreign body was lodged within six inches of the lower edge of the cricoid cartilage, it was best removed by an operation from the side or above, but if situated more than six inches from the cricoid cartilage, gastrotomy was the best thing to be done. He then exhibited a patient from whom he had removed a plate of false teeth by means of gastrotomy.

DR. F. S. DENNIS, of New York City, then read a paper, the title of which was:

REPORT OF AN AMPUTATION AT THE HIP-JOINT FOR THE REMOVAL OF A MALIGNANT GROWTH, SARCOMA,

in which he said that it was only by collecting the cases which occur from time to time, and comparing them, that we are able to advance our knowledge. This case was that of a young man, aged seventeen years, who had no bad family history, and who had always been in good health until about five months prior to his admission in the hospital. At the time of his admission, his weight was eighty-five pounds. Five months prior to his admission, he had first noticed a dull pain in the thigh, and shortly afterwards, he discovered a swelling in the thigh. He had had no fall or blow.

About two months after the first appearance of the pain the tumor was aspirated, and about ten ounces of bloody fluid drawn off. The swelling was fusiform in shape, the skin was purple, and large veins were to be seen on the surface of the tumor while the glands of the thigh and groin were much enlarged. The diagnosis was that it was a sarcoma of the femur, and amputation at the hip-joint suggested, as the only means of saving life. This amputation was done, and the wound dressed antiseptically. The wound was entirely healed by the sixth or eighth day after the operation. After the patient left the hospital the wound reopened a little, and discharged pus mixed with blood. This was found to be due to sloughing of the ligament sutures, upon the removal of which the wound healed kindly, and the young man is now well.

DR. GASPER W. GARMANY then read a paper on the SURGICAL TREATMENT OF EPILEPSY BY TREPHINING,

in which he related the case of a girl about eighteen years of age, struck on the head with a brick falling from a house-top, and causing fracture of the skull. The skull was trephined, and the splinters of bone removed, but some time after the wound had healed she began to have attacks of epilepsy, for which ordinary treatment was unavailing, and the reader finally operated on her, with an entirely successful result. As a result of his researches on the subject, the reader had found that lesions in the frontal and parietal regions are followed, usually, by the same symptoms, and that over fifty per cent. of the lesions in these regions are followed by epilepsy, which, later on, is complicated by insanity. Trephining at the site of the lesion, and removing the cicatrix, is usually followed by complete relief.

The Section then adjourned until 3 P. M.

(To be continued.)

— The returns of the Boston Board of Health show a greater prevalence of typhoid fever during the month of August of the present year than for a series of years past. The following table illustrates the comparative statistics on this point for the month of August in seven consecutive years:

Year.	Cases.	Deaths.
1881	..	18
1882	60	14
1883	135	20
1884	115	25
1885	111	14
1886	136	18
1887	169	23

— That "heart-burnings" should not be a more frequent result than they are of great medical congresses and conventions, is rather a matter of surprise when men who have laboriously built up a wide professional reputation, see their fame scattered to the winds by the typographical vagaries of the "enterprising" medical journalists, with whom celerity of report outweighs accuracy. For instance, Dr. John Homans, the eminent ovariotomist of Boston, appears in the columns of the *Medical Register* (daily), as Dr. John Thomas. In the report of the discussion the only approximation to an elucidation of the personality of this reader is afforded by the remarks of a speaker on the paper of Dr. "Horman."

— Dr. Morell Mackenzie, of London, who had the happiness to achieve so brilliant a success in the treatment of the throat of the Crown Prince of Germany, a success which showed to especial advantage in the focus of public attention incident to the exalted station of his patient, is beginning to reap his reward. He has received the honor of knighthood, and will doubtless receive what may or may not be considered of more value, the sum of $12,500, the amount of his bill for services rendered. The Crown Prince has been spending some time in the Highlands of Scotland, and reports by letter to Prof. Virchow continued improvement in the condition of his throat, while the laryngological examinations show no recurrence of the growth and a decrease in the local congestion.

— Professor Alonzo Clark, M.D., LL.D., died at his home in New York, Tuesday, September 13th. Dr. Clark has been aphasic for some years.

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 15, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE MEETING OF THE INTERNATIONAL CONGRESS AT WASHINGTON.

THE Ninth International Medical Congress being a thing of the past, the reports being all in, and a sufficient time having elapsed since the adjournment for sifting and comparing the observations and conclusions of various reporters and participants, we may venture to draw some more definite conclusions as to the characteristics, the success, and the results of this meeting. Before drawing any such conclusions, we would say that — not having been in sympathy with the impulses of, and the course pursued by, the majority who dominated the American Medical Association at New Orleans, and anticipating, since then, the unfortunate results which could not fail to follow the action taken there, and that subsequently by the enlarged Executive Committee at Chicago and elsewhere — it was our earnest desire not to pre-judge events, and to interpret reports, not merely in a fair, but in as favorable a light as possible, as will be evident from our last week's issue.

The question whether the Ninth International Medical Congress was a success and a credit to those who assumed its management is not, after all, one of "patriotism" or malevolence, any more than the question of official representation should have been made one of square miles of territory, but is simply a question of fact, and, though a question of fact, may be answered somewhat differently, according to the standard of success and credit. As registration could be made by letter, as well as personally, the number of delegates actually present and participating in the proceedings of the Congress can only be estimated. The registration was officially reported as 2,700, and the actual attendance may be liberally estimated at between 2,300 and 2,500, certainly a sufficiently large number to stamp the Congress as a moderate success, at least, from the mere point of view of size. When, however, the enormous domestic medical population is considered, and how slight an impediment a railway journey is to an American who wants to do something, the success from this point of view is hardly more than moderate.

The number of foreigners actually present was really small, possibly 150: and of the long list of vice-presidents read, only one responded to the invitation to come forward and take a seat upon the platform. The distribution of members from the different parts of our own country was very unequal, as was anticipated, the West and Southwest being most largely represented. There were, unquestionably, distinguished Americans and foreigners present at and participating in the Congress, but it is undeniable that distinguished names were conspicuous by their absence, rather than by their presence.

Of the actual value of contributions and discussions it is still early to judge absolutely. In regard to the papers contributed we are inclined to think that the same remark may be made as we have already made about the attendance. There was much disappointment about the papers promised to the General Section — papers usually among the most important — and the Section on General Medicine fell below the standard which should easily have been reached. The Surgical and the Gynæcological Sections were the most active, the latter profiting by an attendance partially attracted by the approaching meeting of the American Gynæcological Society, and also by papers which should have gone to the Obstetrical Section. The officers, and especially the Secretaries, of these Sections deserve credit for great industry. The discussions, some Sections being excepted, were either wanting altogether or very meagre.

The best that could be done under the circumstances probably was done to provide for social courtesies and entertainments; the provision, however, was disappointing and arrangements, on at least two occasions, were insufficient to accomplish the necessary ends or altogether neglected, and on this point we must, upon further information, recall the expression used in our editorial column last week.

Want of money was the cause of the inefficient and insufficient arrangements for social entertainment. The raising of the necessary funds was one of the responsibilities, and one of the most important, which the Executive Committee assumed in assuming its functions and taking control of the preparations. The main reliance seems to have been placed upon securing what might be needed from the public treasury. Secretary Bayard, however, explained in his address, that Americans are not in the habit of looking to Government for the support of educational and scientific interests. Whatever idea the foreign visitors may carry away of other American "institutions" their association with our bands of music and our claret punch, will not be flattering, for if any of them were cheerful — as reported by an esteemed contemporary — at the Pension Hall *conversazione*, it was in spite of these accessories. The season of the year amply accounted for any deficiency in private hospitality.

Much hard work was done by the Secretary-Gen-

eral of the Congress, and by members of the Executive Committee, otherwise the measure of success obtained, could not have been achieved. This was not sufficient to make the ninth Congress the largest, the most interesting, or in any one respect the most useful and important ever held, and it is useless to characterize it as such. A truly polite and amiable foreign delegate might permit himself to speak of it as a *succès d'estime*, but scarcely with more enthusiasm.

The JOURNAL has furnished special reports of the General Sessions, of the Section of General Medicine and Section of General Surgery. No attempt has been made to publish the proceedings of the other Sections. An incomplete report would have no value, and a complete report, if valuable, would attain a bulk inconsistent with a weekly publication. Having looked over the reports of our enterprising contemporaries, we are not disposed to repent our concentration. Such of our readers as find their desires whetted for more, after reading the reports furnished by the JOURNAL, and who are too impatient to await the official volumes, are referred to the daily edition of the *Medical Register*, and to the *New York Record* and *Medical News* of Philadelphia. *Jam satis est!*

Miscellany.

WHAT PROMINENT MEN SAY OF THE CONGRESS.

DR. N. S. DAVIS said to a representative of *The Medical News*, on Thursday evening, in reply to the inquiry whether he thought the Congress had been a success, that in point of numbers it stood second, if not first.

"But as to its character and the scientific value of its work?"

"Well, I have seen all the presidents of Sections to-day, and they each and every one of them report most favorably."

"From your experience of previous Congresses, do you not think there was a conspicuous absence of distinguished foreigners — such men, for instance, as Paget and Gull, and Pasteur and Verneuil, and Virchow and Lister, and others whose names are known all over the world?"

"Yes, that is so; but then you must remember that many of those you name are over seventy years of age, and at their time of life, with their professional duties, a journey across the Atlantic, and such a prolonged absence as is thereby implied, is a very serious matter. Sir James Paget himself told me he feared he would be unable to attend on account of his advancing years. Professor Virchow wrote me that he could not come because of an important conference to be held in Berlin this month, of which he is Chairman of the Committee of Arrangements. I do not remember exactly what that conference was, but it was something combining hygiene with some other subject."

"But what about Neudörfer and Lutaud, of Paris, who were to have been here and to have taken part in the proceedings?"

"Neudörfer is detained by sickness; and Lutaud — well, I can't say anything about him."

"Then, on the whole, do you think the delegates compare favorably with those of other Congresses?"

"Yes, I think so. They are younger men, true, but I understand some very valuable papers have been contributed even by those who did not come. M. Simon, for instance, a very eminent man I am told, has forwarded a most important paper. And you must remember we have had difficulties with regard to the foreign delegates."

"What were those?"

"I do not care to go into them, but, gentlemen — you could count them on the fingers of your two hands — have written and begged foreign delegates not to come. They said there were factional differences. They even went so far as to say that Washington was unhealthy; that the weather was very hot, and that typhoid fever was prevailing. Of course, this kept some away."

"How do you think the American reputation for hospitality has been maintained?"

"That I would rather say nothing about. I have heard many complaints from the foreign delegates that they were not able to get into the White House to see the President and Mrs. Cleveland last night — many such complaints. It was unfortunate, very. I am very sorry it occurred."

"Is there any prospect, do you think, that the Congress will ever meet in the United States again?"

"Not for twenty years, at least. These sessions are only triennial, and it is not likely that Washington's turn will come round again for twenty years, if then."

SECRETARY-GENERAL JOHN B. HAMILTON was asked how many delegates had registered.

"Over twenty-six hundred."

"How many foreigners?"

"Three hundred, it is estimated, but I have not the local registration-book at hand."

"Have you been cramped for want of money?"

"Yes."

"If the dissension beginning at New Orleans had not taken place, do you think there would have been a larger contingent of foreign delegates?"

"If there had been no system of general misrepresentation practised by many of those who resigned, and followed up by personal solicitation to stay away, the attendance might have been larger; as it is, the attendance from Transatlantic countries is larger than it was at former Congresses."

"Do you know of any dissatisfaction having been expressed by foreign delegates as to their treatment here?"

"No, on the contrary, see Sir James Grant's speech to-day, on this point."

"What do you think of the scientific aspects of the Congress?"

"They are entirely satisfactory, and will take rank with any former Congress. I can only view with contempt the statements made with evident intent to disgrace America, and belittle our guests."

"What about the absence of those American physicians who withdrew from the Congress and remain away."

"While their absence is to be regretted, yet the facts show the Congress is entirely successful without them."

DR. UNNA, of Hamburg, being asked "What opinion he had formed of the Congress?" replied:

"I do not think it is of as high a character as those of Copenhagen and London. The discord at home has prevented many foreigners from coming. This discord was so promptly heralded abroad, that it became in a measure international. If it had not occurred many Germans would have come, not thirty or fifty, but two hundred. This number would have included the most prominent men of the country. I regret that the leading physicians of America did not overlook the discords when it was too late to reconsider action, and so give to the Congress more of the air of being international. Men like Agnew, Loomis, and others, are much missed. My strongest impulse in accepting the vice-presidency, and reading a paper, was to prevent the Congress from dwindling into simply a national affair. I regret that others did not take the same view. The scientific aspect, although not equal to former Congresses, is better than was to be expected under the circumstances. Papers in the Dermatological Section were good for the most part, but the discussions were poor; but such is the case at all Congresses. Socially I have not had much personally to complain of, although I am aware of many deficiencies. I know that many errors have been committed. The arrangements have been poorly announced. On the whole, there is much to be regretted."

Dr. W. T. Lusk, of New York, was asked what opinion he had formed of the Congress.

He replied: "I have heard some complaints from foreign delegates regarding a want of courtesy on the part of the officers of the Congress. It seems there has been some want of business management, and perhaps a lack of experience on the part of the officials in managing such affairs. They have been too much disposed to regard the foreigners as they would our own people, who are always willing to look after themselves, while a European seems to require some one to take care of him."

"What do you think of the scientific value of the Congress?"

"I believe the volumes of Transactions, when published, will be equal, in respect of the papers contained therein, to those of any preceding Congress."

"If the unfortunate dissension which began at New Orleans had not occurred, would not the success of the Congress have been more marked?"

"Well, I must say, the presence of prominent members of the profession at the discussions was greatly missed."

Dr. Lusk, who was somewhat unwilling to give his views for publication, also stated that he thought that in the division of papers between the Sections of Obstetrics and Gynæcology, the former had been unfairly treated by being deprived of several papers properly belonging to it.

Dr. Mariano Semmola, Professor of Therapeutics in the University of Naples, Italy, was asked his opinion of the present Congress, and replied to the queries addressed to him as follows:

"You have attended other Congresses?"

"Yes; indeed, I think I have attended every one."

"What opinion have you formed of the scientific value of the Congress?"

"It is considerably below the average of any of its predecessors."

"Do you think that if the unfortunate dissensions at New Orleans had not taken place, that a larger number of distinguished men from Europe would have attended this Congress — such men as Porro, from your own country, and Pasteur, Virchow, Esmarch, Paget, MacCormac, etc.?"

"I have met many, if not all those gentlemen at preceding Congresses, and have no doubt at all that if there had been no quarrel among the profession here, some, if not all of them, would have crossed the Atlantic."

"How did you happen to come yourself?"

"I was assured that the quarrel was a matter that had entirely passed over, and so I came on."

"Have you met many of the Americans whom you expected to see?"

"Very few, indeed, and it is a matter of sincere regret to me."

"How have the social aspects of the Congress appeared to you?"

Dr. Semmola smiled at the question, shrugged his shoulders and said: "Well, I have had one or two private invitations, but as for the rest — it does not exist."

"You are not favorably impressed then?"

"No; how can I be?"

Correspondence.

[From our Special Correspondent.]

LETTER FROM WASHINGTON.[1]

Notes and Gossip about the International Medical Congress.

Washington, Saturday Evening, Sept. 10, 1887.

On Friday evening Secretary Whitney, of the Naval Department, gave a reception to the foreign members of the Congress at Grasslands. It is understood that the host himself was absent. He was represented by an officer of the navy, and lunch was served to the visitors, but the foreigners are understood to wonder if American hosts usually consider their duties end with the issuance of the invitations.

It is said that 2400 bottles of champagne were consumed at the Pension Hall banquet of Thursday.

It is a little noteworthy that Secretary Bayard, who made the address of welcome at the opening of the Congress, is understood to be the most pronounced homœopath at Washington.

A reasonable verdict as to the Congress seems to be that it was, considering the circumstances, fairly successful, and no more. The gentlemen who came from abroad had a right to expect to come to a representative American gathering; and this they failed to find. Sectional as regards residence, scant in men of recognized professional eminence, the American contingent of the Congress was a body of very worthy family doctors. The whole registration, by the Secretary-General's count, was 2,700, which means an actual attendance of between 2,000 and 2,500. The number of foreign members was not far from 150; and of these there were but few of wide fame. As to the papers presented, quantity, not quality, seems to have been the rule. Instead of the two papers a day before the general session, which should have been the marked features of the Congress, lack of material reduced them to one daily, and of these, one, in the author's own words, was written merely to be read before a Section. The address of the President of the Congress fell heavily upon the listening ear. There were, doubtless, among the sectional papers, some that were worthy of preservation. Time alone will sift the big wad of documents, which ambitious young men of inexperience combined with respectable practitioners to accumulate; but it is believed that the world would weep at the loss of few of them. There inheres, of necessity, in every gathering of the sort, a wonderful power of attraction for cranks and wind-beaters; and there was no lack of these among the authors of papers or among those who discussed them. In certain sections, like that on gynæcology, for example, where were present eminent men from abroad (attracted it may be, by the meeting the succeeding week of the American Gynæcological Society, to which they had been specially invited) discussion meant more than mere words. But this could not be said in all cases.

As a means for the advancement of science, the success of the Congress was questionable.

So far as the local arrangements were concerned, the job appeared to be too big for the Committee in certain directions; at least the Chairman of the Committee expressed publicly his dissatisfaction with his own arrangements in as strong terms as did any mere member of the Congress.

The charm of the weather, the beauty of the city, the courtesy shown the Congress by the Chief Executive of the country, all favored the gathering. What it might have been under proper auspices can but be imagined.

"SHORT CUTS" TO DIPLOMAS.

Boston, 130 Dartmouth Street,
September 5, 1887.

Mr. Editor,— In justice to Professor Sewall's indignation (September 1st), to "Reader" (August 11th), and to the University of Michigan, let us notice that "the same college" in "Reader's" letter, does not mean the University of Michigan, but as it reads, it does mean in all probability the one mentioned in the original letter to the *New York Medical Record*, "The University of ——— situated among the hills of New England." If any reader will take time to look up that first letter he can easily establish the connection of the later ones and also recognize the college referred to.

By the way, I know a case in point: a student in the University of Michigan was "plucked" in February, immediately left for New York and returned with his diploma in April, to laugh at his class that had to "grind" until June.

Very truly yours,
C. P. Pengra, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 3, 1887.

Newburyport	13,716	7	1	14.28	14.28	14.28	—	—
Northampton	12,896	—	—	—	—	—	—	—

Deaths reported 2,477: under five years of age 1,153; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 648, consumption 299, lung diseases 158, diarrhœal diseases 392, diphtheria and croup 88, typhoid fever 80, malarial fevers 35, whooping-cough 22, scarlet fever 17, cerebro-spinal meningitis seven, measles four, puerperal fever three, small-pox (New York) two. From malarial fevers, New York 11, Brooklyn and New Orleans eight each, Philadelphia and Baltimore two each, Boston and Charleston one each. From whooping-cough, Philadelphia eight, New York and Boston five each, Pittsburgh two, Brooklyn and Lawrence one each. From scarlet fever, New York, Boston, and Pittsburgh, three each, Brooklyn two, Philadelphia, Baltimore, District of Columbia, Nashville, Lowell and Holyoke one each. From cerebro-spinal meningitis, New York three, Boston, District of Columbia, Fall River and Holyoke one each. From measles, New York two, Brooklyn and Pittsburgh one each. From puerperal fever, District of Columbia, Pittsburgh and Somerville one each.

In the 21 cities and greater towns of Massachusetts, with an estimated population of 1,017,117 (population of the State 1,941,465) the total death-rate for the week was 22.78 against 21.60 and 27.05 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,244,099, for the week ending August 20th, the death-rate was 23.3. Deaths reported 4,128: infants under one year of age 1,755; acute diseases of the respiratory organs (London) 178; diarrhœa 878, whooping-cough 100, measles 87, scarlet fever 61, fever 35, small-pox (Sheffield) four.

The death-rates ranged from 15.0 in Derby to 33.5 in Manchester; Birmingham 24.5; Blackburn 30.8; Hull 27.6; Leeds 21.5; Leicester 18.2; Liverpool 26.7; London 21.2; Nottingham 20.9; Sheffield 21.8.

In Edinburgh 16.9; Glasgow 19.5; Dublin 35.5.

The meteorological record for the week ending September 3, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Week ending Saturday, Sept. 3, 1887.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

CONDITIONS FAVORABLE TO OUT-OF-DOOR LIFE IN COLORADO.

BY SAMUEL A. FISK, A.M., M.D., DENVER, COL.,
Professor of Diseases of the Nervous System, University of Denver, Col.; Member of the American Climatological Association; etc.

Of all the methods that have arisen, of late years, to aid in the arrest, or cure, of Pulmonary Consumption, there has not yet been found one to take the place of change of climate. Even the most ardent advocates of gaseous enemata, of deep inhalations, or of deep injections do not claim for their methods superiority to the climatic treatment, but the most they can urge is that they may be valuable adjuvants, or, at least, that they can be profitably employed, when through financial, or other reasons, a change of climate is impossible. Assuming, then, that the climate is the best treatment known in the arrest, or cure of consumption, or in prophylaxis, the question arises as to which is the best climate. This is a much debated point, and the weight of evidence is often, in the mind of the reader or listener, based upon the esteem in which the one giving utterance to the opinion is held. There are those who contend for a sea air, and others for a mountain air. "Many people," says Dr. Hermann Weber, "still cling to the idea that cold is injurious and warmth curative in phthisis, but this idea is quite incorrect. Another idea, that equable climates are the best in the treatment of phthisis, should likewise be much restricted."

However various the opinions, on two points there is, practically, unanimity: —

(1) That the air should be pure, aseptic, free from germs.

(2) That it should conduce to life out-of-doors.

The former condition, that of an aseptic atmosphere, has been shown by Professor Tyndall, Miguel and others, to belong to elevations of 6,000 feet and over; such an elevation as is to be found along the slopes of the Rocky Mountains, in Colorado, Wyoming and New Mexico.

The conditions that conduce to out-of-door life are those that render life in the open-air not simply tolerable but attractive, so as not only to make the invalid feel that he *ought* to be out-of-doors, but that he *wants* to be. How far these conditions are fulfilled by a life in Colorado, it is my purpose to show.

An important element, perhaps the most important, in making life out-of-doors attractive is that the sun should be shining. Clouds depress, sunshine exhilarates, and between two climates equally good in other respects — if indeed such a thing can be imagined — that one in which the sun shines the most hours in a day and the most days in a year, should be selected for the mental effect — if for none other.

I wish to speak now of sunshine, disregarding, for the present, its effects upon temperature, dryness, (atmospheric and soil), the processes of growth and blood formation, etc. Some years ago[1] I pointed out by the following table that, of the twelve places included in the list, selected with reference to their geographical location, and taking a mean of five years, there were fewer cloudy days in the eastern slopes of the Rocky Mountains than in any other portion of our country.

[1] Science, October 5, 1883.

Cloudy Days. Mean for Five Years.

Augusta, Ga.	92	Chicago,	107
Jacksonville,	87	St. Paul,	104
Boston,	115	Denver,	46
Newport,	111	Santa Fé,	41
New York,	109	Salt Lake,	93
Philadelphia,	112	Los Angeles,	51

The data on which this assertion was based were derived from the Signal Bureau, U. S. A. — and the conclusion I drew was: — "It is seen that, in Denver there is only about one-eighth of the entire year where an invalid would be kept in the house on account of the weather; in Jacksonville and Augusta he would be confined to the house for the same reason, one-quarter of the year; in St. Paul he would be kept indoors between a third and a quarter of the time, while in Boston he would have to be housed a good third of the time."

These facts were questioned, and the methods of deriving them criticised, by the late Edward T. Ely, M. D.,[2] and the objection was raised that the hours for taking the observations that furnished these figures were 5 A.M., 1 and 9 P.M. (local time) and that the two hours 5 A.M. and 9 P.M., coming at night, were of no interest to the Colorado invalid in estimating the amount of time that he could spend out-of-doors, because of the clearness of the sky.

To meet this objection I compiled the following table, the data being derived from the U. S. Signal Bureau.

Cloudy Days. Winter, 1884-5.

Months.	Denver Time.			
	9.08, A.M.	1.08, P.M.	5.08, P.M.	All Day, 9 A.M.–5 P.M.
September	2	0	3	0
October	7	2	5	1
November	3	4	6	1
December	11	9	9	1
January	5	5	3	1
February	9	9	5	1
March	4	5	7	3
April	12	5	6	3

The conclusion drawn was:[3] "While there occurred days in the winter, under observation, when the sun was not shining at 9 A. M., or at 1 P. M., or at 5 P. M., as the case might be, there were only eleven days in the whole eight months when the heavens were completely obscured at all three observations. In other words, there were only eleven days in the winter of 1884–1885 when the sun did not shine upon Denver between the hours of 9 A. M. and 5 P. M."

The same subject has been represented, diagrammatically, in maps furnished the Colorado State Medical Society by the United States Signal Bureau, at the request of the former. These maps, copies of which, with a reduced scale, I here introduce, are of interest, more as giving the ratios of cloudiness, than because they show the relative amounts of sunshine.

My reasons for making this assertion are that they are compiled from observations taken, the country over, at 7 A. M., 3 and 9 P. M., Washington time, two of the three observations being, practically, for most places, in the night (the corresponding times for the Rocky Mountains region being 5 A. M., 1 and 9 P. M.). Furthermore, in order to show the actual number of hours of sunshine at any given place, a self-recording instrument, of the Draper or other pattern, should be used to jot down the record for every minute of the

[2] New York Medical Journal, July, 1884.
[3] Popular Science Monthly, March, 1886.

day. Such instruments are not introduced into the Signal Service Stations, nor has there been any in operation, in Colorado, until quite recently, when three of the stations of the Colorado Meteorological Association have supplied themselves with them. These three instruments have, however, been in operation too short a time to furnish the required data.

Turning, then, to these maps, it will be seen that, in the spring of 1882, while the highest percentage of cloudiness in the United States was from $\frac{6}{10}$–$\frac{7}{10}$, in Denver it was from $\frac{4}{10}$–$\frac{5}{10}$ the minimum being $\frac{2}{10}$ around Yuma.

In the summer of the same year, Denver was $\frac{3}{10}$–$\frac{4}{10}$, as against a highest $\frac{5}{10}$–$\frac{6}{10}$, in the East, and a lowest $\frac{1}{2}$ of $\frac{1}{10}$, in lower and Western California. In the autumn, Denver was in the portion of the country freest from clouds, the cloudiness being only $\frac{2}{10}$, and in winter it was still in the least cloudy portion, the cloudines being only $\frac{3}{10}$.

These maps show that in the autumn and winter months, Denver, which may be taken as standing for Colorado, was in the portion of the whole United States where the sky was least obscured by clouds, while, in the spring, it was about mid-way in the scale.

In considering the amount of sunshine, as influencing the extent to which an invalid can be out-of-doors, it is fair to speak not only of the number of days in a year in which an invalid can enjoy the sunshine, but the number of hours in each day. At present, we can only show this by comparison with other resorts, and by giving the hours of sunrise and sunset.

The much-famed Davos has, according to Dr. Hermann Weber,[4] on the average, four hours and sixteen minutes per day during November, and four hours and forty-five minutes during January. This is due to its position, being located in a long and narrow valley, where the sun comes over the mountains late, and sets early.

In treating of this subject, Dr. Tucker Wise[5] gives the following table of sunrise and sunset for the first day of January:

	Sunrise.	Sunset.
Malaja	9.35, A.M.	3.45, P.M.
Wiesen	10.35 "	3.45 "
Pontresnia	8.30 "	3.10 "
St. Moritz	10.00 "	3.05 "
Davos Platz	11.03 "	3.00 "
Andermatt	11.45 "	3.15 "

By way of comparison, I introduce

Denver	7.30, A.M.	4.57, P.M.

I do not mean to say that what is true of Denver in regard to the hours of sunshine is true of each and every portion of the State; but I do assert that it is true of most of the places of resort, and that the geographical conditions for length of sunshine that exist at most of the resorts of Colorado are beyond comparison with that of most health-resorts, for here the sun rises early over a boundless plain, and rolls on an unobstructed course to a late setting beyond the distant mountains.

Whatever the advantages, then, that come from uninterrupted sunshine — and many claim, amongst the chief of these, an increased production of blood-corpuscles — whatever the advantages that come from uninterrupted sunshine, they are to be enjoyed to the full in Colorado.

Another factor in enticing an invalid to a life out-of-doors is not alone that the sun should be shining, but that the temperature should be comfortable. It is on this point that the Colorado climate has been most severely criticised by those who are without any personal experience of it, and it has been difficult to carry conviction to the minds of such that the assertions that have been made with respect to the comfort of being out-of-doors at mid-day in the very heart of winter, in this climate, have been true.

We, who have written on the subject, have asserted the facts time and again. We have told of going around, day after day, without overcoats; of sitting with open doors and windows; of sitting out-of-doors in shirt-sleeves; and of picnicking in mid-winter, only to be met with the: "But doesn't the mercury ever go below zero?" "Yes, occasionally it might. "Then it must be cold, where the mercury is below zero." Such persons are not to be blamed, never having experienced the difference, in feeling, between the same temperature in the damp air of the sea-board and the dry air of an elevated region, like that of the Rocky Mountains, they cannot appreciate the truth of Dr. Franklin's[6] remark that: "Even with a much lower thermometer, the air, if still, feels warmer at an elevated station than in lower and denser regions of the atmosphere, in consequence of the slower abstraction of heat from the body."

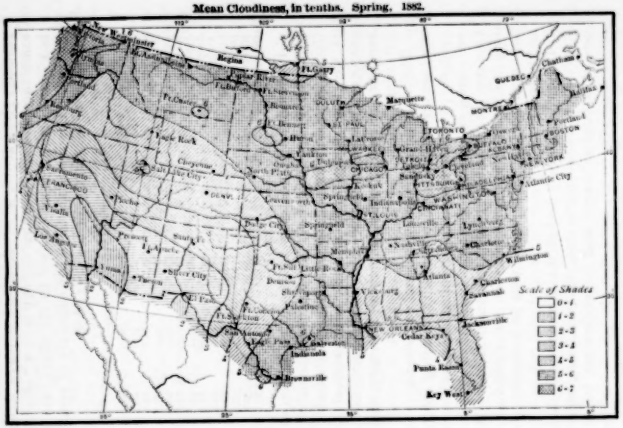
This explanation of the "slower abstraction of heat" should be borne in mind in interpreting the figures in the accompanying table, which gives the mean temperature at Denver, Col., for the eight months, September to April, inclusive, at the hours of 9.08 A. M., 1.08 and 5.08 P. M.

MEAN TEMPERATURE, 1884–85.

	9.08, A.M.	1.08, P.M.	5.08, P.M.
September	67.4	75.4	74 6
October	56.2	61.1	64.1
November	41.6	53.3	49.9
December	25.6	32.5	26.8
January	27.0	35.8	33.3
February	31.9	38.0	37.8
March	41.3	48.2	47.7
April	47.7	53.9	54.3

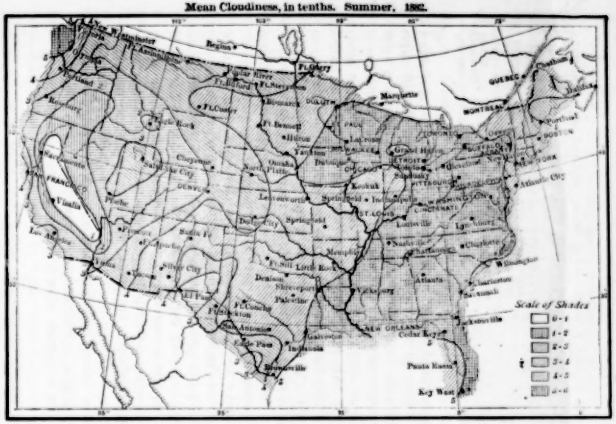
Furthermore, it should be remembered that these temperatures are the readings of a thermometer in the "shelter-box" of the local Signal Station, placed 100 feet or so, above the ground — and, so far as possible removed from the sun's rays and the influence of solar radiation.

This factor, solar radiation, is of great importance in considering the day temperatures of Colorado; one that can be explained by figures, but not thoroughly understood, save from personal experience. Says Prof. Edward Franklin, M. D., F. R. S., whom I have already quoted: —



"The sun's rays are far more powerful at great, than at low elevations, and their intensity is much more equable throughout the day."

It is the *intensity* of the sun's rays, added to the *slower abstraction of heat* from the bodies that makes the day temperatures of Colorado enticing to an invalid for an out-of-door life; that makes it possible to sit with doors and windows open, and to picnic even in the middle of winter.



Not until recently have we been able to give figures in corroboration of our assertions, but for a year or more, the Colorado Meteorological Association has been taking observations with a solar thermometer (a blackened-bulb thermometer *in vacuo*) placed at the same elevation as the signal thermometer from which the

[4] Croonian Lectures, 1885, p. 83.

[6] Popular Science Monthly, July, 1885.

Mean Cloudiness, in tenths. Spring. 1882.

Mean Cloudiness, in tenths. Summer. 1882.

Mean Cloudiness, in tenths. Autumn. 1882.

Mean Cloudiness, in tenths. Winter. 1882.

readings given above, were taken, and exposed to the same surroundings save that the one is in a "shelter-box" and the other is exposed to the direct rays of the sun. The following table is a summary of results for the 1 P. M. reading for the year 1886.

MEAN TEMPERATURE. 1 P.M.

1886.	Solar.	Air.	Difference.
January	92.5	27.3	65.2
February	106.3	48.0	58.3
March	107.8	41.1	66.7
April	110.6	52.3	58.3
May	141.3	74.3	67.0
June	142.2	75.1	67.1
July	146.5	85.2	61.3
August	143.7	81.5	62.2
September	122.3	72.0	60.3
October	119.5	64.2	55.3
November	100.0	41.3	58.7
December	100.2	45.5	54.7

It should not be necessary for me to go into an explanation of these figures. They prove conclusively that it is possible for one to be around in the sunshine of the noon hours, even in mid-winter, without an overcoat; that it is possible to sit out-of-doors, *in the sun*, even in December, or January, or February, without being chilled.

The sensation is most novel and exhilarating. A sun-temperature of great intensity beating down upon one while he is constantly being bathed with the refreshing coolness of the air. I cannot describe it! One can theorize about results as he may please. He may say that the extremes between the air temperature and the sun temperature must be injurious and not to be borne.

I know, and every one of the thousands of inhabitants of Colorado knows, that, far from being injurious, it is most salutary; that it renders life out-of-doors wonderfully attractive; that one goes swinging along, in mid-winter, unimpeded by unnecessary wraps, with a step of bouyancy and a feeling of intense exhilaration.

With these factors of which I have spoken, a large percentage of sunshine, and a temperature of sufficient warmth to do away with over-coatings and wraps, what life does not open to our invalid!

Be he quite delicate, he can sit in a sequestered nook, away from draughts and winds, and bathe for hours in the genial warmth of a hot sun, while he is breathing an aseptic, dry, rare air. Be he more vigorous, he could do as is most common with our invalids, he can ride or drive, he can play croquet, tennis, or what not, — in short, he can be out-of-doors, almost constantly from sunrise to sunset and be pleasantly occupied the while.

It may be that in making these assertions I am forestalling things that should first have been said. Life in the air would not be so enticing were there rain, or snow, or fog. To be sure, it can hardly be true that there will be much rain, or snow, or fog where there is so much sunshine; yet to clear up any doubt and to state the matter positively I introduce the following table giving the total amount, in inches, of rain or snow (melted) that fell each month of the year 1886.

PRECIPITATION, 1886.

January	0.62	July	0.50
February	0.72	August	1.62

Total	14.87		

I will further state, that having had occasion to investigate the subject, some time since, I found that there was *not a single fog* recorded at our signal station during the months September to April inclusive, in 1884–85, as occurring between the hours of 9 A.M., and 5 P.M. Fogs do occur, but so rarely as almost to warrant the assertion that such a thing does not exist in Colorado.

One more factor I wish to speak of as favorable to out-of-door life in Colorado, and in this connection I may say that here, as in all else I have said, I make especial reference to the months that constitute an invalid's winter. September to April inclusive — and that is that this life out-of-doors is led on a dry, sandy, porous soil, free, almost the entire time, from any covering of snow and absolutely dry.[1] It is not my object to speak of soil-moisture in its relation to the production of consumption, a subject so ably treated of by Drs. Bowditch and Buchanan, but rather to urge the advantage to be derived from being out-of-doors on an absolutely dry, sandy, soil.

How could our invalids lead the life they do were there snow and ice on the ground? Horseback riding would be impossible, and this constitutes the chief exercise of our invalid population, and even driving would be uncomfortable. I say would be, because sleighing is a condition of things nearly unknown in Colorado. When snow falls, as it sometimes does, to the extent of fourteen inches or so, the intense solar heat, and warm winds soon melt it, and the porous soil soon drinks it up, and like Aladdin's palace it is gone. Of course this freedom from snow does away with wet feet, so common when there is snow, and with the inevitable and distressing "thaw."

The advocates of ice-and-snow-covered soils, such as exists in the Engadine in winter, trace its advantages to two sources; namely,

(1) It prevents dust and decay, and the microbe-laden evacuations from the soil (Hermann Weber).

(2) It influences the sun-temperatures by reflecting the solar rays from the snow (Franklin).

To show how unimportant this latter factor becomes, I quote figures from observations taken in the "Maloja," by Dr. A. Tucker Wise, and compare them with my own, already introduced.

MEAN SOLAR RADIATION.

Maloja.	Fahr.	*Denver*, 1 P.M.	Fahr.
November, 1883	115	November, 1886	100.0
December, 1883	89	December, 1886	100.2
January, 1884	105	January, 1886	92.5
February, 1884	108	February, 1886	106.3
Average	103.75	Average	99.75

In regard to the prevention of dust and decay and microbe-laden emanations from the soil, chapters might be written. It might be asked, for instance, whether decay and microbe-laden emanations will not be produced to an exaggerated degree by the thawing of the ice and snow that have kept them dormant for months; and whether this thaw will not come at these resorts at times when they should be especially in demand, because of the inclemency of the weather at the invalid's home.

The microbe-laden emanations are also the results of putrefaction, and can hardly be applicable to the vast extent of mountains, or the boundless plains, where there is but little animal or vegetable matter to decompose. In communities the prevention of these emanations must be a matter of sanitation.

[1] This is not always true of Denver, where the soil is more alluvial and is sometimes muddy, but it is true of the State at large, and especially of such places as Colorado Springs, Poncha Springs, Boulder, Idaho Springs, etc.

Perhaps the heaviest charge to be laid at our door as regards the prevention of out-of-door life, is the question of winds. While the average daily velocity in miles at Denver, is much less than in Boston, as is shown by the following table, yet it sometimes happens that we have high winds, which, in a city like Denver, where the streets are not paved and there is no snow upon the ground, picks up the dust and makes a so-called "dust-storm."

VELOCITY OF WIND, 1880.

	Spring.	Summer.	Autumn.	Winter.
Boston	257	184	223	281
Denver	156	143	115	127

In places like Colorado Springs, Boulder, Idaho Springs, Poncha Springs, etc., where the soil is more gravelly and where there are not any narrow streets, through which the wind can sweep, as through a funnel, dust-storms are infrequent. Even in Denver the days in which there was a wind of eighteen miles, or over, for two consecutive observations of the three, 9 A.M., 1 and 5 P.M., during the year 1886, were as follows:

HIGH-WINDS, 1886.

January	1	July	0
February	5	August	1
March	1	September	1
April	1	October	3
May	2	November	6
June	0	December	2

There were, in addition, about an equal number of times when there was a wind, of eighteen miles or over, at only one of the three observations.

These figures, I know, can carry but little idea, for unless one is acquainted with the methods of taking observations the simple statement that a wind is blowing eighteen miles an hour does not convey much information. It is nothing like a tornado, and perhaps should not be called a high wind. Many would speak of it as a pretty stiff breeze.

In mentioning the aseptic air, the clear weather, warm sun, dry soil, freedom from fogs, etc., as amongst the attractions that conduce to life out-of-doors in Colorado, I must not forget to add to them the vast number of natural objects that awaken interest and excite the curiosity.

There are mountains, and dells, and caves, and cañons to be explored; remarkable and grotesque formations in rock to be visited; an almost unknown Flora and Fauna to be studied, and upheavals and wonderful geological formations to be noted. There are mountains, on the one hand, with all the attractive features of life amongst the eternal hills, and plains close by to be roamed over at will, as one drifts about over the rolling sea.

Space will not permit of my going into detail, the guide-books and other writings are full of descriptions; and so I will draw what I have to say about the attractions to an out-of-door life in Colorado, to a close, by quoting from a remarkably impartial article written by the late Dr. Ely, who, himself an invalid, kept close observation of the weather of Colorado Springs. "From the 1st of September (1883) to the 1st of May (1884)" he writes: "I have been confined to the house by bad weather forty-two days — that is, there have been forty-two days (out of two hundred and forty-two) on which I have not been able to go out even one hour, and such may be fairly reckoned as days indoor. Of the remaining days there have been many when I should only be out from two to four hours, and when being out was a burden to the flesh. This record is satisfactory enough for me."

He then concludes his article as follows: "Colorado can easily afford to rest on its own merits, which are indisputable, and is only injured by much of the indiscreet praise bestowed upon it by its friends. Despite all objections which may be raised, the climate is, probably, as we have already said, the very best of its kind at present available for invalids, and destined to grow in popularity as its merits become more accurately understood."

ATYPICAL TYPHOID FEVER, WITH REPORT OF A CASE.

BY H. LAWRENCE JENCKES, M.D., HAZEL GREEN, WISCONSIN.

THE typical or common form of this disease is too familiar to require any description in this article. The report, however, of a case in which the temperature during most of the patient's illness was subnormal, may be of interest.

In a lecture on the subject by James C. Wilson, M.D.,[1] at the Philadelphia Hospital, he divided the atypical forms into the following classes; namely,

(*a*) Mild typhoid; (*b*) abortive typhoid; (*c*) typhoid of childhood (infantile remittent); (*d*) typhoid of the aged; (*e*) cases of febrile intestinal catarrh; (*f*) cases of afebrile intestinal catarrh. It is to this last and rare form that I would direct attention.

The writer was called on the 20th of April, 1886, to see a child ten years of age who had been unwell for several days. His tongue was slightly coated, bowels constipated. Pulse 100, temperature 100°, under the tongue when it was taken at each examination. At this visit he was given a dose of calomel and bismuth, and a Dover's powder left to be taken at bedtime. The calomel produced several free evacuations from his bowels during the night.

On the afternoon of the next day there was little change in his condition, his headache had not abated, pulse 100, temperature 101°. He was ordered a fever mixture. The next afternoon his pulse and temperature were 110 and 102.2° respectively. A milk diet was ordered. On the 24th there was no headache, but the pulse was 118, temperature 103.5°. No tympanites, but marked tenderness in the region of the ileo-cœcal valve. The case was pronounced one of typhoid fever, and the patient put upon the so-called "specific treatment" of carbolic acid and tincture of iodine, which caused so much nausea, however, that, after a few days it was discontinued, and the previous fever mixture was resumed.

On the afternoon of the 26th, the patient seemed worse. He would answer questions very slowly; his abdomen was slightly tympanitic and tender on pressure, pulse 118, temperature 101°. It will be noted that the temperature fell 2.5° on the seventh day of treatment, and about the tenth day of his illness. As he had not been overwhelmed with quinine or antipyrine, it could hardly have been the result of treatment. On the 27th, a moderate diarrhœa set in, with pulse 120, temperature 99°; in all other respects the condition was unaltered. There was no change on the 28th, but on the 29th the tympanites had increased, and blood appeared in the discharges; pulse 124, temperature 98°. For six days, until May 5th, there

[1] Medical News and Abstract, July, 1881.

was little change in any of the symptoms. Rose spots appeared upon the abdomen, the pulse ranged from 118 to 124 and temperature from 98° to 99°.

From the 5th to the 18th, the pulse remained about 115 to 120, and the temperature about 98°. On the 19th his pulse fell to 108, after a profuse perspiration, and his temperature was 98.5°. After the 20th no record was kept, but on the 24th the temperature was normal, the pulse 100. The patient was quite cheerful and sat up an hour that day. The only striking feature of this case is in connection with the temperature which remained at 98° for about three weeks, with all the other symptoms of severe typhoid fever, well marked. This case, with a few others that have been published has a tendency to prove that elevation of temperature *is not absolutely necessary* in cases of typhoid fever, although the general belief is that it is excepting in mild cases.

In looking over the literature at hand upon the subject, I can find but few cases reported. Hartshorne says:[2] "An attack of disease, in which, on the second day, the heat in the axilla is as high as 104°, is not typhoid fever, and the same exclusion applies if, from the fourth to the eleventh day, the temperature falls below 103°."

Fräntzel[3] reports the following: "Several cases of typhoid fever which attacked exhausted individuals, and which ran their course with low temperature, or without fever, but in which occurred general collapse, serious cerebral symptoms, and tendency to gangrene of the extremities, which run a strikingly acute course. Such cases indicate that high temperature is not the only cause of death in typhoid fever, but that cerebral symptoms are of great importance, and that patients even with low temperature must be carefully watched, to prevent them from the many evil consequences of even quiet delirium."

In the article on typhoid fever by Liebermeister,[4] cases are mentioned in which the temperature is not high (afebrile cases), but such cases are classed as mild. He attributes more significance to the character of the temperature than to any other symptom of the disease.

Professor Flint[5] says: "More or less increase of the heat of the body is invariable. The rule that, during the greater part of the disease, the temperature is raised is without exception; but, under certain circumstances, the heat may not exceed, and it may even fall below, the standard of health."

In a review article[6] I find the following: "Mr. J. V. Lentaigne's case of fatal peritonitis, following perforation of an ulcerated small intestine, is of very great value with reference to the diagnosis of enteric fever and the occurrence of afebrile cases of that disease. The patient from whose body the specimens were taken came from a notoriously unwholesome tenement, in which thirty-three or thirty-four persons lived in eight apartments. Seven deaths had recently occurred, and one man was then sick abed. Furthermore, the main sewer of the street had been for some weeks "open." The man had been ill for about a fortnight, and had been refused admission to three hospitals. When received into the Jarvis Street Hospital, although manifestly ill, his temperature was normal, and the difficulty in diagnosis appeared to be due to this fact. The autopsy discovered the lesions of enteric fever. The writer of this review has elsewhere insisted upon the fact, too little recognized, that enteric fever may run its course not only without the typical temperature of Wunderlich, but even with a sub-febrile temperature; and, in certain rare cases, the nature of which is established by the complexus of symptoms and the coexistence of house epidemics, actually without any rise of temperature at all. It is a quibble to say that such cases are not enteric fever. They are the specific enteric disease, of which the usual fever is merely one of the prominent, but not, therefore, always essential symptoms."

From this imperfect review of the subject, the following may be deduced:

(1) The typical course of Wunderlich does not occur in all cases of typhoid fever.

(2) Even severe cases are occasionally seen in which the temperature does not exceed the normal.

(3) That it is unnecessary, and may even be hurtful, to direct the treatment *solely* to the reduction of the fever, but that symptoms must be met as they arise.

REPORT ON PROGRESS IN DISEASES OF THE CHEST.

BY F. C. SHATTUCK, M.D., BOSTON.

MORTALITY FROM CONSUMPTION AMONG THE TROOPS IN THE UNITED KINGDOM.[1]

AN important paper on this subject was read before the Statistical Society of London in January, 1887, by Robert Lawson, LL.D., Inspector-General of Hospitals. The periods embraced were from 1837 to 1846, and from 1860 to 1884, there having been no returns from 1847 to 1858.

It is shown that there has been a marked reduction in the mortality from consumption in the military, just as in the civil population.

There is a very general belief that the great reduction of consumption in the army was due to improved ventilation in barracks; this was commenced in 1859, and was pretty generally introduced in 1862, and should immediately have begun to show its effects. The mortality from consumption in 1860–62, however, was 5.80 per 1,000, and that of 1864, 5.56 — a reduction of 0.24 only after two years' full operation of the ventilation — while, in 1865, the ratio was 4.84, or full three times as great which followed the substitution of flannel for linen or calico shirts in 1864; and this low ratio continued, with little alteration, for the next fifteen years. Up to 1823, the troops wore cloth trousers in summer. That year, white linen was introduced instead, which were often put on damp, and without any under-clothing. In 1846, a light woollen material was introduced in place of the linen. So far as the records enable an opinion to be formed, the introduction of the linen was followed by a large increase of deaths from consumption, and the substitution of woollen material, in 1846, was followed by an equally remarkable reduction. In 1880–84, the mortality from consumption between the ages of eighteen and forty-five in civil life was 2.81 per 1,000; in the army, 2.70 per 1,000.

[1] Dublin Journal of Medical Science, March, 1887, p. 311.

It would appear that the causes chiefly concerned in reducing consumption, lately, at least, are such as improve the general health.

ASTHMA: ITS ETIOLOGY AND MECHANISM.

Glasgow [2] has made laryngoscopic examinations in a number of cases of asthma during the paroxysms. He was led to this course by a previous study of a peculiar condition of the nasal mucous membrane encountered in "persons of a marked nervo-vascular temperament, and in whom functional nerve disturbances were common." This condition is characterized by pallor, swelling, and œdema; any irritation of the membrane is followed by an increase in the swelling, and the pouring out of a thin, watery secretion. The swelling subsides on the inhalation of ether and amyl nitrite, or the application of atropia or morphia, but is not influenced by cocaine. The pathology of the condition is thought to be vaso-motor spasm of the arterioles of the membrane.

During an asthmatic paroxysm, a similar condition of things can be observed in the pharynx, and also in the larynx and trachea, the swelling, however, being less marked in the latter than in the former. Glasgow thinks it fair to infer that the bronchial mucous membrane shares in this condition. "I would, then, consider asthma to be a disorder of vascular irritability; that the paroxysm is directly due to a partial occlusion or cylindrical narrowing of the lumen of the bronchi, through the swelling of the bronchial mucous membrane; that this swelling is caused by a vaso-motor spasm of the arterioles, with a saturation of the tissues by the liquor sanguinis. This condition is accompanied by a general high blood-pressure.

"With this theory, we find a complete explanation of all the physical signs of asthma. We see the possibility of the rapid changes of physical signs observed during the paroxysm, and we have in its support the physiological action of all the drugs which experience has found to be of value in allaying the paroxysm. The nitrite of amyl, morphia, chloral, lobelia, and iodide of potash, in their action, allay the spasm, at the same time that they tend to reduce general blood-pressure, whilst drugs like the bromides prove of less value in breaking the paroxysms when once in force, although they are serviceable in preventing a recurrence."

In connection with the above paper, it is of interest to abstract briefly a recent paper of Professor Fraser,[3] who thinks that the changes which take place in asthmatic dyspnœa under the influence of the nitrites can be explained only by the acceptance of the old and long generally-received theory that the essential feature of bronchial asthma is spasm of the muscular coat of the bronchioles.

"The first observations I made with these objects in view was in 1880, on a patient twenty-two years of age, of markedly nervous diathesis, who had suffered from asthma for several weeks. The chest was auscultated during an asthmatic paroxysm of moderate severity, and it was found that cooing, whistling, and creaking râles were abundantly present. She inhaled, during fifty seconds, a few minims of nitrite of amyl. Two minutes after the inhalation had been commenced the râles had entirely disappeared, and her breathing had become quite easy. In another minute the râles had returned, and the breathing had become more difficult. After an interval of six minutes, when both the râles and the dyspnœa were present in their original abundance and severity, she again inhaled nitrite of amyl, this time for thirty seconds, and in forty-five seconds after commencing the inhalation the râles had entirely disappeared, and the breathing was perfectly unembarrassed. In five minutes afterwards, the original state of breathlessness, with its accompanying auscultatory phenomena, had returned. After an interval of ten minutes, nitrite of amyl was a third time inhaled, with essentially the same results as on the previous two occasions."

This observation has been since repeatedly verified, other nitrites and nitro-glycerine being used. Also in bronchitis accompanied with dyspnœa, similar results have been obtained, the breathing becoming easy, and the dry râles disappearing. Of the class of remedies under consideration, the author prefers nitro-glycerine and nitrite of sodium, both stable compounds, and capable of subcutaneous introduction into the system.

It will be noticed that Glasgow attributes the effects of the nitrites to their action on the unstriped muscle of the arterioles; Fraser, to their action on the unstriped muscle of the bronchioles.

PNEUMOTHORAX IN APPARENTLY HEALTHY PERSONS.[4]

Dr. de Haviland Hall reported, at a meeting of the London Clinical Society, a case of pneumothorax coming on suddenly, and gradually disappearing without leaving any traces behind it. He, at the same time, gave brief abstracts of four similar cases which he had found in literature. Dr. Hall, as well as most of those who took part in the discussion, thought it probable that a latent and limited tuberculosis was present in most of these cases. Dr. Burney Yeo said that, during ten years' experience at Brompton, he had never met with such a case as those described by Dr. Hall. He supposed that sufficient stress had not been put on dry pleurisy as a cause for the condition. This form of pleurisy might easily escape notice, or be discovered only by accident.

SUDDEN DEATH IN PLEURISY.

This important subject is carefully studied by Weill,[5] who has collected, and, as far as the scanty details of many of the cases will allow, analyzed twenty-seven cases. His conclusions are of special interest in that they differ, as will be seen, in some respects from those generally entertained.

The principal conclusions to which the author's studies have led him are as follows:

(1) Sudden death in pleurisy seems to be referable to certain lesions, the chief of which are thrombosis and embolism of the heart and pulmonary artery, œdema of the lung of the other side, and changes in the myocardium. The latter are often overlooked, inasmuch as their detection requires the aid of the microscope.

(2) It is not possible, at present, positively to affirm or deny the dependence of sudden death in pleurisy on simple functional disturbances, such as syncope; mechanical causes, like dislocation of the heart, twisting of the vessels, rectangular bending of the ascending vena cava; or hypothetical lesions, such as capillary embolism of the brain.

(3) Sudden deaths occur in all kinds of pleurisy,

[2] Am. Jour. Med. Sciences, July, 1887.
[3] Lancet, 1887, II, p. 51.
[4] British Medical Journal, 1887, I, p. 618.
[5] Revue de Médecine, January 10, 1887.

whether right or left; acute or chronic; in the increasing, stationary, or declining stage. The fluid is generally serous.

(4) Pleurisy terminating in sudden death may or may not be accompanied by such special symptoms as attacks of dyspnœa, premonitory faintness, irregular pulse, or displacement of the heart. Often death comes on at a time when the patient seems to be doing extremely well. It generally follows motion or exertion.

(5) Treatment, though powerless in cases of myocarditis or thrombosis of the peripheral veins, has a prophylactic value in cases of another nature. This preventive treatment is thoracentesis.

THE OPERATIVE TREATMENT OF ABSCESS OF THE LUNG (QUINCKE).[6]

A man of twenty-six was admitted into hospital with an abscess in the left lower lobe, the result of pneumonia two years before. The expectoration was not at first offensive, but became so after a fresh attack of pneumonia in the right lower lobe, apparently due to aspiration of the secretion from the cavity. The cough was very troublesome, and irregular fever was present. The examination showed that the abscess-cavity was connected with one or more bronchi, that it was lined with a smooth membrane, and surrounded by thickened tissue, but that the pleural layers over it were not adherent. The latter conclusion was warranted by the fact that the movements of the affected side were not limited, and the portions of the left lung bordering on the heart and spleen moved freely in respiration.

The indication was clear to incise and drain the cavity, but the author's previous experience had taught him the danger of such a procedure when the pleural cavity, at the point of section, is not obliterated by firm adhesions. A cut was, therefore, made June 2d, in the eighth interspace through the skin and muscles, and in the cut was placed chloride-of-zinc paste. July 2d, a fine trocar was thrust into the line of incision without result. July 9th, it was again inserted and left in place, but replaced several days later by a lead-sound. The result was again negative, as was also puncture in another spot, followed by the thermo-cautery. August 21st, an inch of the ninth rib was resected, and the thermo-cautery was worked into the lung to the depth of an inch. Several other fruitless attempts were made to reach the cavity, which finally, September 14th, opened itself through the wound. Drainage was not, however, satisfactory, and it seemed that the cavity did not communicate directly with the wound, but was connected with it by a bronchus.

The following month, portions of the sixth, seventh, and eighth ribs were resected, with the hope of allowing the chest-wall to fall in, and thus aid in the obliteration of the cavity. This hope was not realized, and the patient did not wish to undergo any more rib-resection. In December, he left the hospital and resumed his occupation — locksmith. In the last three-and-a-half years he has worked steadily, has married, and is a father. He has no cough or expectoration. The cavity still discharges, but the patient wears an ingenious contrivance of his own, which saves him any great inconvenience from the discharge, which is perfectly sweet.

[6] Berliner Klin. Wochen., 1887, No. 19, p. 337.

While he was in the hospital, the discharge was repeatedly examined for bacilli, without result.

The report of the case is followed by remarks on the literature of the subject, and reasons for the great importance of making sure that there is pleural adhesion before operative treatment is resorted to in these cases.

AORTIC ANEURISM AND AORTIC ATHEROMA IN CHILDREN.[7]

Aneurism is a very rare disease in childhood. Roger, in 1863, showed a specimen of aortic aneurism in a child of ten years, and Crisp then reported that, out of 551 cases of aneurism, only five occurred in persons whose age varied from a few days to twenty years. In this paper, Sanné gives notes of four cases. The first, observed by Phaenomenon, was found in the body of a still-born child. The aneurism, which affected the abdominal aorta, was ten centimeters in breadth, and eleven centimeters in length. The structure of the arterial coats is said to be "altered," but in what way is not stated. The second case, that of Roger, was in a child of ten years, who had all the physical signs and clinical features of aneurism of the arch of the aorta, but was taken out of hospital before death. Case 3 was observed by Sanné himself: a child of thirteen years suffered for six months from cyanosis, dyspnœa, with occasional œdema of the legs. The physical signs showed dilatation of aorta and insufficiency of the aortic valves; death in three months. Section: hypertrophy of left ventricle; dilatation of aortic arch; atheroma and thinning of its walls, with a small sac at the top of the curve; aortic valves incompetent and atheromatous. Fourth case, reported by Moutard-Martin, had not an aneurism, but the heart was greatly dilated, and the aortic valves and aorta itself showed patches of atheroma; this child was ten years of age. A fifth case was shown by Dr. Norman Moore to the London Pathological Society, in 1882, from the body of a child of five years. The symptoms and physical signs are the same as in the adult; no information as to the etiology is given.

VALVULAR DISEASE OF THE HEART AS A CAUSE OF EPILEPSY.

Lemoine[8] reports three cases in which the disturbances of the cerebral circulation secondary to imperfectly-compensated valvular lesions seemed to be causative of epileptic attacks. The latter entirely ceased, or grew far less frequent, after the administration of cardiac tonics — digitalis and caffeine. Two of the cases were of mitral, one of aortic disease. In the former, of course, the tendency is to venous congestion of the brain; in the latter, to arterial and general anæmia. A possible result of either of these opposing conditions is convulsion.

DILATATION OF THE RIGHT AURICLE.[9]

Schrötter lately found in a case dulness in the right side of the chest, near the sternum, over an area corresponding to the situation of the right auricle. In order to determine whether the dulness was due to a dilated auricle, or to an encapsulated pleural or pericardial effusion, he inserted a needle, and obtained

[7] Centralblatt für Kinderheilkunde. Edinburgh Medical Journal, August, 1887, p. 188.
[8] Revue de Médecine, 1887.
[9] Fortschritte der Med., 1887, No. 13, p. 415.

only pure blood, thus establishing the diagnosis of dilated auricle.

Death occurred later, apparently in no way hastened by the puncture, and marked tricuspid stenosis was found to be the cause of the increase in the size of the auricle.

SPARTEINE AS A HEART-TONIC.

In the "Report on Progress" for March 4, 1886, the high recommendation of this drug by Sée was noticed. Since that time the remedy has been tested by others, all of whom do not join with Sée in rating it higher than digitalis. Among these are Voigt, who used it in Nothnagel's clinic, and Stössel,[10] who reports on its use in Schrötter's clinic. The drug was given in valvular disease, Bright's disease, and cirrhosis of the liver. Its action is similar to that of digitalis, but is less powerful, and no diuretic effect was obtained. "Digitalis is superior to sparteine in every respect," and is to be used only when the former disagrees, or as a substitute, the former having been already used with good effect.

VALVULAR DISEASE OF THE HEART KNOWN TO HAVE EXISTED FOR OVER FIVE YEARS WITHOUT CAUSING SERIOUS SYMPTOMS.

Sir Andrew Clark[11] finds in his case-books, between the years 1873 and 1886, "684 cases in which there existed chronic valvular disease of the heart, the presence of which was not indicated by symptoms, and did not sensibly interfere with health; and if I were to add to this number the instances which I have not recorded, the instances which I have failed to discover, and the instances which I have met with in consultation with other medical men, the number would be raised to a thousand."

These 684 cases are tabulated and analyzed: 326 of these were led to seek advice by disorders or diseases of the digestive system; 134 by disorders of the nervous system; 81 by rheumatic affections; 47 by respiratory disturbance; 30 by cutaneous diseases; and 23 by gout.

Some most interesting and instructive cases are detailed, among them cases in which the health first began to suffer after the patients were told by their physicians that they had heart disease.

In the great majority of cases of chronic valvular disease of the heart, it is not only safe, but desirable to recommend the patient to return, in a more or less modified degree, to a strict observance of the physiological conditions of life as respects diet, clothing, exercise, and occupation. But, "when the heart is irritable, frequent, intermitting, or irregular; when the murmurs vary in character and intensity; when there is any suspicion that recent changes have been occurring in the interior of the heart; and, more especially, when there is any febrile disturbance of the system, it is necessary that the patient should be kept at rest, and fed upon the lightest food."

Another point of very great interest and importance is well brought out by the author; namely, that inflammatory changes in the valves may, in the course of time, quite disappear, leaving no trace behind them. Thus organic weakness may, after lasting some years, vanish entirely.

"And now, turning to another side of our subject, let me ask, concerning a given case of valvular heart lesion — say, for example, a case of mitral regurgitant disease — what are the conditions which, assuming, on the part of the patient, obedience to properly-adjusted rules of health, would justify us in permitting him to continue the ordinary duties and enjoyments of life, in sustaining an application for life-insurance, in sanctioning marriage, and in speaking favorably of his prospects of longevity. Well, according to my experience and judgment, these conditions are as follows:

"(*a*) Good general health.

"(*b*) Just habits of living.

"(*c*) No exceptional liability to rheumatic or to catarrhal affection.

"(*d*) Origin of the valvular lesion independently of degeneration.

"(*e*) Existence of the valvular lesion without change for over three years.

"(*f*) Sound ventricles, of moderate frequency and general regularity in action.

"(*g*) Sound arteries, with a normal amount of blood and tension in the smaller vessels.

"(*h*) Free course of blood through the cervical veins.

"(*i*) Freedom from pulmonary, hepatic, and renal congestion.

"Here it must be said, as a matter of course, that the conditions of a favorable prognosis would differ for different valves, and for each valve, according to the character of the lesion. A comparatively small 'loading' might justify assurance, in a favorable case, of mitral regurgitant disease, whilst no 'loading,' however heavy, for a time however short, would warrant acceptance of a case of regurgitant disease of the aortic valves. If, in the former case, the risks to be incurred were to be reckoned as one, then, in the latter case, the risks to be incurred would have to be reckoned as a thousand. The person with aortic might possibly live as long as the person with mitral disease, but there would be such small security for the transaction, that, considering the possibilities of disaster, it could not be regarded as other than a reckless speculation."

This most valuable paper concludes with the following propositions:

"(1) That there are many persons with long-standing valvular disease of the heart engaged in the active business of life, who, without any symptom of heart disorder, enjoyed good health, and have reached an advanced age.

"(2) That the mitral regurgitant murmurs so often encountered in chorea for the most part disappear within eight or nine years of the attack.

"(3) That valvular inflammations and their effects, arising in the course of rheumatic fever, do sometimes disappear, and leave behind no clinical evidence of their former existence; and that this, occurring for the most part in the young, also occurs sometimes in the middle-aged.

"That the signs of valvular defects arising out of the degenerative changes of middle life do also, on rare occasions, disappear, and that, when circulatory and respiratory disturbances accompany their commencement, they sometimes subside, and permit of apparently complete re-adjustment.

"(5) That as there must be in the histories, habits, occupations, and surroundings of patients with valvular disease conditions which, in one case, bring about secondary disorders, and, in another case, exempt it

[10] Centralblatt f. d. Gen. Therapie, 1887, p. 163. Fortschritte der Medicin, May 15, 1887.

[11] British Medical Journal, 1887, I, p. 260, 325, 370.

from them, it is desirable that the respective differentiæ should be discovered, and made capable of application to practice.

"(6) That any systematic and critical study of this subject likely to lead to practical issues should be undertaken only by the Collective Investigation Committee, and not by it unless actively assisted by experienced general practitioners, who possess, in a special manner, the knowledge necessary to the end in view.

"(7) That a joint inquiry of the kind proposed, conducted with due patience, discrimination, and accuracy, would greatly extend our knowledge of the natural history of diseases of the heart, and largely increase our means of assisting those who suffer from them."

Clinical Memorandum.

AN ACCIDENT WITH COCAINE.

BY ALBERT N. BLODGETT, M.D.

On the afternoon of April 25th, 1887, I was visited in my office by Dr. J. R., aged twenty-three years, who has always been well and strong, and is not addicted to the use or to the abuse of any stimulant or narcotic. He desired to consult me in relation to a small growth situated upon the right side of the face, at a point about half an inch in front of, and on the level of the superior border of the tragus of the right ear. The growth had been noticed but a few weeks before, and had caused no inconvenience, but on account of a supposed predisposition to the development of malignant disease in his family, the discovery of this small tumor had given rise to some degree of anxiety in the mind of the patient. The patient was in perfect health, pulse sixty, and had been employed all day in his usual avocation. Dr. R. had used cocaine to a considerable extent in his practice for the purpose of producing local anæsthesia in the operations of minor surgery, and suggested that this agent should be employed by subcutaneous injection in his face. I agreed to this, and injected three minims of a twelve per cent. solution, which he had brought with him, and which had been specially prepared for the occasion. The syringe was one of mine, and had not been used previously to this occasion. All air was carefully evacuated from the shaft and needle of the syringe, and the cocaine was injected at two points, one in front and the other behind the tumor, care being taken to avoid the location of the facial nerve, the parotid gland, and the larger vascular channels of this region. Thirty seconds after the injection was made the patient began to complain of a feeling of great depression, a sensation of coldness, and of faintness. It was thought at first that these sensations were due to fright, or to an undue amount of apprehension as to the action of the drug; but this proved to be erroneous. The patient rapidly became cyanozed, the breathing changed to a sighing character, the pulse was one hundred and forty and weak, the face was bathed in cold perspiration, there were short periods of profound collapse with unconciousness. The patient was assisted to a couch, where he soon became quite helpless. Stimulants were administered, the heat of the surface was maintained, the body warmly covered. At the expiration of a quarter of an hour the finger on the pulse showed a commencing improvement in the patient's condition. With the restoration of the organic functions, came a mild form of delirium, the patient talking incessantly upon all possible subjects, and apparently not realizing that he had been in any abnormal condition. Soon the pulse was reduced to eighty per minute, and the skin became warm. The delirium gradually subsided, and the patient slowly returned to his natural state. Another injection of two minims of cocaine was now made in the periphery of the tumor, and after waiting for a few minutes, the small growth was quickly and painlessly removed. The patient remained somewhat excited and was unusually loquacious for some hours afterward, but had no return of the collapse or any other sign of impending danger.

I have thought that possibly the first injection was of too large amount, and by its sudden presence in the vascular system, may have dangerously affected the central organs of circulation, or the higher nervous centres. The latter would seem the most probable explanation, as the effect was developed with a degree of rapidity which I have never seen equalled by any other drug which I have ever used by subcutaneous injection. I was incredulous when the patient began to complain of the effects of the injection, for I thought it too soon for any effect whatever to be produced, but the clammy perspiration, the lividity of the face, the accelerated pulse, the weakness, the loss of conciousness, the sighing respiration, and the general collapse proved that it was not fright alone, for the patient was not afraid of the drug; but that it was due to the action of the substance upon the most important structures of the body.

I was much impressed at that time by the report of the fatality which had then recently occurred in Russia in consequence of the use of cocaine, and for a time feared that some unfortunate result might follow in this case, but I now think that the collapse was not of sufficient gravity to warrant so grave apprehension. I shall, however, endeavor to secure the action of the anæsthetic on future occasions by slower administration of the drug, and thus hope to avoid a repetition of this disagreeable experience.

Reports of Societies.

AMERICAN DERMATOLOGICAL ASSOCIATION.[1]

ELEVENTH ANNUAL MEETING.

THURSDAY, SECOND DAY. — MORNING SESSION.

At the business meeting, the following officers were elected: President, Dr. I. E. Atkinson, of Baltimore; Vice-President, Dr. P. A. Morrow, of New York; Secretary and Treasurer, Dr. G. H. Tilden, of Boston.

The report of the Committee on the Congress of American Physicians and Surgeons was received and adopted. Dr. I. E. Atkinson, of Baltimore, was appointed representative to the Executive Committee of the Congress, and Dr. G. H. Tilden, alternate.

The first paper read was by DR. E. B. BRONSON, of New York, presenting a

CLASSIFICATION OF DISEASES OF THE SKIN.

The classification was made upon an anatomical

[1] Concluded from page 259.

basis. Cutaneous affections were divided into the following five classes: (1) idioneuroses; (2) angioses; (3) epidermidoses; (4) cryptoses; (5) dermoses. Diseases of the skin were further divided into sub-orders, tribes, families, genera, and species.

DISCUSSION.

Dr. P. G. Unna, of Hamburg. We can never have a complete, definite, scientific classification of affections of the skin. As the knowledge of disease progresses, so must our classifications change. The ideal classification would be one made, not upon anatomical, but upon an etiological basis.

Dr. L. D. Bulkley, of New York. I would express great admiration for the classification which has been presented, but I think that it is hardly suited for practical, every-day use. As an attempt to scientifically classify diseases of the skin, it is far in advance of any classification yet offered.

THE DIAGNOSIS OF DERMATITIS HERPETIFORMIS,

by Dr. L. H. Duhring, of Philadelphia.

The author had been led to believe, from the perusal of various reports of cases, that this affection was not thoroughly understood. He, therefore, thought it desirable to offer some remarks with reference to its diagnosis. The chief characteristic of the affection is the multiformity of its lesions manifested in the natural evolution of the disease. If a given case remain sufficiently long under observation, multiformity of lesion will sooner or later be noted, and this will repeat itself.

Blebs, vesicles, and pustules may appear together or separately. Mixed eruptions are the most common, vesicles predominating. In one attack or another, only one kind of lesions may be present. The disease presents clearly-defined characters in distinct elementary lesions, and certain distinctive abortive lesions. Secondary forms of lesions also exist. Pigmentation of a dirty yellow or brownish hue, and variegated, is usually a marked feature in chronic cases. Excoriations from scratching, with thickening of the skin, usually exist. In no other affection are such varied combinations of lesions met with as in dermatitis herpetiformis.

Erythema and vesicles, or vesicles and blebs, or blebs and pustules, frequently exist, side by side, in close proximity, with more or less pigmentation, excoriation, and secondary changes. Itching is usually a most distressing symptom, and is most severe in the vesicular variety. In the pustular form, subjective symptoms may be wanting. The disease is extremely chronic, extending over a number of years. In two cases under the author's observation, the duration had been thirteen and eleven years, respectively, and the disease was still active, with no prospect of cure. The eruption tends to recur at variable periods, usually six or eight weeks.

Some cases of dematitis herpetiformis closely resemble cases of erythema multiforme, but the lesions of the former disease are less sharply defined, and the course of the two affections is different, erythema multiforme being an acute disease of short duration. The disease occasionally resembles herpes iris, but the chronicity of the affection would exclude herpes iris. The lesions are also more virulent, and accompanied with a more profound degree of cutaneous disturbance. Herpes iris is a benign affection, running an acute course, and terminating in recovery, although subject to relapses. When the bullous varieties exist alone, they may resemble pemphigus vulgaris. The combination with other lesions will, however, prevent any confusion in the diagnosis.

With reference to the term dermatitis herpetiformis, the author stated that he had adopted it in preference to dermatitis multiformis, for the reason that there was already a disease named erythema multiforme, and the use of the term dermatitis multiformis might lead to confusion, and give rise to the opinion that its was simply an advanced stage of erythema multiforme.

DISCUSSION.

Dr. L. D. Bulkley, of New York. I wish to briefly report a case showing some of the difficulties of diagnosis. A man was admitted to the hospital with remarkable skin lesions, and the case was regarded by all who saw it as one of dermatitis herpetiformis. The patient was suffering with fever, and the temperature remained high until death. In connection with the lesions of the skin, there was general alopecia of the body. At the autopsy generalized sarcoma was found, affecting the spinal cord and various internal organs. Whether or not the cutaneous lesions were simply the manifestation of the internal disease, I cannot say.

The President, Dr. H. G. Piffard, of New York. I cannot help thinking that the author has included in his description diseases of quite different nature. Some of these cases are analogous to the old hydroa, others may be of septicæmic origin, while possibly, some may be the result of local irritation. It seems unphilosophical to consider these different conditions under one head. I have seen, as the result of bites of insects, lesions corresponding to those described in some of the cases of dematitis herpetiformis. I should hardly consider such a case an example of this disease.

THE TREATMENT OF LEPROSY,

by Dr. P. G. Unna, of Hamburg.

The speaker, after referring to the fact that leprosy was usually considered incurable, and that as a consequence, treatment was not resorted to, stated that he had recently treated five cases of this affection with encouraging results. The treatment consists in the external use of the following ointment:

Chrysarobin	Five parts.
Ichthyol	Five parts.
Salicylic acid	Two parts.
Vaseline	One hundred parts.

This is applied to the nodules on all parts of the body with the exception of those on the face, neck and hands. In the latter situations pyrogallic acid is substituted for the chrysarobin in the above formula. Such an application may be continued for months. For some of the older nodules, this is not sufficiently strong. For these the author employs salicylic acid or salicylic and chrysarobin in the form of a plaster on muslin. This is allowed to remain two or three days or a week. Under this application the tubercles disappear.

In the five cases treated by this method, there has been a rapid disappearance of the leprous matter in the skin. There also was in these cases a decided improvement in the general condition, although no internal remedies were given, the object being to test the efficacy of the external applications.

DISCUSSION.

DR. P. A. MORROW, of New York. I have recently had the opportunity of treating a number of cases of leprosy, and I believe that certain cases of leprosy are as responsive to chaulmoogra oil, as are cases of syphilis to mercury. In the case of a Norwegian, the subject of tubercular leprosy, the lesions have disappeared and he has apparently recovered under the use of chaulmoogra oil. On a number of the nodules of the face, I used caustic potash, and they disappeared very rapidly. Some cases, however, fail entirely to respond to this treatment.

The President, DR. H. G. PIFFARD, of New York. Some time ago I treated a case of leprosy in a young man from Bermuda. When he entered the Hospital, he was unable even to dress himself. He was given a preparation containing strychnine, and in six weeks was engaged in rowing a boat across the river. I have also used nux vomica in as full doses as the patient would tolerate. I am in the habit of associating this with the external use of chaulmoogra oil.

AFTERNOON SESSION.

THE USE OF MEDICATED RUBBER PLASTERS IN CERTAIN CUTANEOUS DISEASES,

by DR. H. W. STELWAGON, of Philadelphia.

The speaker had employed rubber plasters containing a certain percentage of various substances, such as chrysarobin, pyrogallic acid, ammoniated mercury and oxide of zinc. The special field of these plasters is in the treatment of certain chronic affection, such as sluggish patches of eczema, psoriasis, callosities and ring worm. A ten to twenty per cent. plaster of salicylic acid is useful in the treatment of callosities. In the treatment of lupus vulgaris the effect obtained from the pyrogallic acid plaster was equal to that obtained by the use of the ointment. Chrysarobin plaster has been used with advantage in ring worm. The application may be allowed to remain in position one or two weeks.

DR. P. G. UNNA, of Hamburg. In the plasters which I have employed, the plaster mass is spread upon muslin much more flexible than that on which the rubber plaster is spread. The adhesive material which I have employed has been either the oleate of aluminium or the best india rubber. As little of the adhesive material as possible is employed, not more than two to five grammes to the square metre. The strength of the plaster is reckoned, not by percentages, but as so many grammes of the active agent to the square metre.

SALT IN DERMAL HYGIENE AND THERAPEUTICS,

by DR. H. G. PIFFARD, of New York.

Ordinary sea water contains two per cent. of saline matter. It also contains an organic matter which gives to the skin a slimy feel after coming out of the bath. On entering sea water at a temperature of 70° a momentary chill is experienced, which soon passes off. In the course of half an hour a second chill is felt, due to the gradual abstraction of the body heat. This persists as long as the individual remains in the water. In robust individuals, who leave the water before the occurrence of the second chill, sea-bathing may prove beneficial, but in feeble individuals, the sea-bath, as ordinarily taken, is apt to result in harm, mainly, he thought, through abstraction of the body heat by the water. The local effects upon the skin coincide with the general effects. In vigorous individuals psoriasis and chronic eczema will often be benefited by a short bath followed by rubbing. If the patient be feeble or the bath prolonged, the result will be unfavorable. Prickly heat, pruritic affections and furuncles are often benefited by sea-bathing. The principal precautions with reference to sea-bathing are not to go into the water when it is too cold and not to remain in it until the occurrence of the second chill.

The author had also experimented with artificial brine, varying in strength from 5% to 25%. When the percentage reaches 25%, the change can be detected by the feeling. If genuine sea-salt is used, the sticky, clammy feeling is apparent. If white salt is employed, there is a sensation of extreme cleanliness. A 5% solution, used as a bath at a temperature of 95%, and the immersion continued fifteen to twenty minutes, removes the bodily odors and exudations better than a bath with soap, and the body remain free from odor for a longer period than if soap has been used. The skin presents a condition of softness not seen after any other bath. A bath of a 20% to 25% salt solution had been also used with no irritating effect except upon the mucous membrane. In this strength of solution, the water does not seem to wet the skin but rolls off, leaving the body dry.

In acute eczema the use of ordinary water is as a rule followed by temporary aggravation of the trouble. In these cases a full bath of 0.5% to 1% solution had been used with great comfort to the patient. In subacute eczema, psoriasis, furuncles, in irritable summer rash, whether papular or pustular, and in ulcerating syphilides, a 5% solution of salt may be used with great advantage. The salt water should be used as hot as can be borne, the bath continued fifteen to twenty minutes, and should be taken just before retiring. Genuine sea-salt is not so good for the bath as coarse white salt, on account of the slimy feeling which is left. The therapeutic effects are identical.

DR. E. WIGGLESWORTH, of Boston. Was any effect upon the growth of the hair observed?

DR. PIFFARD. My observation in reference to this point is limited to my own person. I have, this summer, noticed an unusual growth of body-hair. Whether or not this was due to the daily use of a strong saline bath, I cannot say.

TWO CASES OF TYPICAL IMPETIGO SIMPLEX,

by DR. L. H. DUHRING, of Philadelphia.

Considerable skepticism exists concerning the existence of a distinct disease entitled to the name impetigo simplex. Impetigo is one of the rarest of cutaneous affections.

CASE I. A boy, aged four years, and well nourished, was brought to the author with the history that, two weeks previously, he had some itching, and this was followed by the appearance of white nodules. Shortly after this, pustules formed. They appeared a few at a time, lasted several days, and then dried up. At the time of observation, there existed about two dozen lesions upon the fingers, toes, and legs. These were typical pustules of the size of a split pea, raised about one line above the surface of the surrounding skin. They were seated upon bright-red, non-indurated bases. They were discrete, and manifested no tendency to group. Microscopical examination did not

reveal the presence of any micro-organisms in these lesions. The process ran its course in about three weeks, no local or internal treatment being employed.

Case II. A boy, aged four years, perfectly healthy, presented a discrete pustular eruption, which had appeared seven days previously. Twenty or thirty small pustules, with a slight areola, were found. They were most marked on the fingers and toes. The pustules had thick walls, and showed no tendency to rupture. There was no itching. The disease terminated in spontaneous cure in two or three weeks. The disease in neither of these cases appeared to be contagious.

A CASE OF PURPURA WITH CIRCINATE LESIONS,

by Dr. H. W. Stelwagon, of Philadelphia.

The patient, a strong and robust man, came under observation in April, 1887. The abdomen was found to be the seat of a macular, reddish-yellow eruption of annular form. The lesions were about the size of a dime. Most of them were almost completely annular in form. The eruption was most profuse on the anterior part of the trunk. The lesions were of a hæmorrhagic nature, there being no hyperæmia. The eruption had appeared as small white spots, three months previously, above the umbilicus, and had gradually extended. There were no subjective symptoms, and the general health was good. The case remained under observation for three weeks, and then was not seen for four months. The eruption had then almost disappeared. The whole duration of the case was about nine months.

So far as the author was aware, only one other case of this character had been reported, and that was put on record by Drs. Duhring and Harlingen.

The last paper was entitled

PROTEST AGAINST EXCESSIVE STRENGTH OF LOCAL APPLICATIONS (OFFICIAL AND OTHER) IN SKIN DISEASES,

by Dr. S. Sherwell, of Brooklyn.

(In the absence of the author, the paper was read by the Secretary.)

The author claimed that most of the local applications of the pharmacopœia were too strong to be used with safety. Instead of diluting these preparations, it is better to order a preparation of the desired strength, for after a preparation has been kept some time, it seems to become more irritating. Numerous illustrations of the views expressed in the paper were given.

The Society then adjourned.

[Special Report for the Journal.]

THE NINTH INTERNATIONAL MEDICAL CONGRESS.[1]

SECTION ON GENERAL SURGERY.

WEDNESDAY, THIRD DAY — AFTERNOON SESSION.

FISTULA IN ANO OF THE HORSE-SHOE VARIETY,

by Samuel Benson, M.D., of London, Eng.

The objects of this paper, as stated by the author, were, first, to point out that an important cause of the failure of the operative treatment of anal fissure is the presence of a coexistent horse-shoe fistula, left unrecognized and untreated. Second, to define what is meant by a horse-shoe fistula, and to comment upon the different kinds of horse-shoe or semi-circular fistulæ met with in practice.

Fissure is such a common complaint, that, doubtless, cases have come under the notice of all present. This malady, if taken early, is very amenable to medicinal treatment; but in many cases, especially in females, the disease is allowed to progress for some length of time before it is brought to the notice of the surgeon, and some operative treatment then becomes necessary. There is a form of fistula, horse-shoe or semi-circular in shape; namely, the blind, internal, horse-shoe fistula, which, though far more common than the complete horse-shoe fistula, is not referred to in any books that I have consulted. Some writers mention the blind, internal fistula which commences in an abscess, but the fistula referred to by the speaker does not commence with an abscess. It is merely a subcutaneous ulceration, extending between, and separating the mucous from the muscular coat of the bowel, just inside the anus, and usually commences in a fissure that has been of some months' duration. A fissure that has been neglected, or treated alternately by caustics and emollient ointments, soon drifts on to the formation of a painful rectal ulcer, with its base of an ashy-gray appearance, and the edges of the sore well marked.

While forcibly dilating the sphincter, it is quite possible that the mucous membrane may sometimes be torn from the sphincter muscle, especially around the parts near the anal ulcer, and a sinus made traumatically. Therefore, when the patient is under an anæsthetic, the examination with a blunt-pointed probe should be made at the base and sides of the fissure before the sphincter ani is interfered with. A blind, internal fistula can then sometimes be demonstrated.

Horse-shoe fistulæ, as at present understood, are complete fistulæ, the external opening being situated on the opposite side of the bowel to the internal opening. This kind of fistula is rare, having been found five times in 750 cases of rectal disease.

From these cases, we gather that fistula in ano of the horse-shoe shape may be complete or incomplete. Horse-shoe fistula may be complicated with prolapsus. The most usual complication is anal ulcer. Sometimes polypus is also found. The average age of the patient is thirty-five years, males and females being attacked indiscriminately. The average number of days in bed is fourteen. If a correct diagnosis is made, the treatment consists in laying open the sinus, and paring the edges with scissors, dividing or paralyzing the sphincter muscle, and packing it systematically with cotton-wool, to prevent the edges sticking together, and getting the wound to heal from the bottom.

A paper by Arthur Trehune Norton, F.R.C.S., London, England, was then read by the Secretary, in the absence of the author. It was entitled,

REMARKS ON RODENT ULCER OF THE RECTUM,

in which the author declares that there is an ulcer of the rectum, persistent, unyielding to treatment, advancing to complete stricture of the rectum and usually appearing after thirty years of age.

The ulcer begins immediately within the anus, after a time extending and completely surrounding the rectum; it is accompanied by a pain which is not usually

[1] Continued from page 268.

severe, and as it extends up the rectum constriction takes place with all the signs of stricture. Treatment by dilatation sometimes relieves for a time.

From the clinical features of the disease and the microscopical characters, the author was of the opinion that the disease was identical with rodent ulcer and suggested that further investigation into its pathology be made.

The discussion which followed related to the treatment of fistulæ in general, and was participated in by Dr. Foster, of Bieracth, Syria, Dr. Quimby, of Jersey City, and Dr. Grant (Bey) of Egypt, who all related cases and agreed as to the proper method of treatment.

DR. GRANT (BEY), then read a paper entitled,

REPORT OF SOME CASES OF LIVER ABSCESS AND THEIR TREATMENT,

in which he gave as his deduction from the result of the cases the opinion that in all cases of liver abscess we should first aspirate the abscess and if that was not followed by cure then lay the abscess open, by a free incision and in extreme cases excise a portion of the ribs (one or more) over the site of the abscess so that free access might be had for clearing out the abscess cavity thoroughly with antiseptics.

In the discussion which followed, Dr. Winslow, of Baltimore, Dr. Pascal, of Mexico, and Dr. Moore took part, and while all agreed as to the principle of treatment, each had his own particular way of arriving at the same result.

DR. LEWIS H. SAYRE then followed with a paper on

THE TREATMENT OF PSOAS ABSCESS BY POSTERIOR LUMBAR INCISION,

in which the author strongly insisted on the early and free posterior and anterior incision in these abscesses, and this to be followed by thorough drainage.

DR. EDWARD OWEN, of London, opened the discussion which followed and spoke long and earnestly, strongly deprecating "ostrich surgery" in these cases, and advising early opening of the abscess with free drainage.

DR. SPRENGLE, of Dresden, thought that in many cases there would be absorption of the pus if we waited for it, and if we opened the abscess it was best to do it with an aspirator or fine trocar.

DR. LANGE spoke of the constitutional treatment, along with the surgical, and thought that he would not open these abscesses if he could avoid it, until after the acute stage had passed.

DR. CHAVASSE, of Birmingham, England, thought it best to open these abscesses as soon as possible, and give the sufferers a chance.

A paper on

THE REMOVAL OF SEQUESTRA BY SOLUTION IN ACID,

by DR. EDMUND ANDREWS, of Chicago, was then read, in which the author gave his experiments in detail, and related a number of cases in which the sequestra had been removed by the use of acids without operation. He recommends that hydrochloric acid be used of a strength a little weaker than the official dilute acid.

FOURTH DAY, THURSDAY, SEPTEMBER 8TH.
MORNING SESSION.

The first business of the meeting was the discussion of the paper of DR. RICHARDSON, read on Wednesday.

GASTROTOMY FOR FOREIGN BODIES IN THE ŒSOPHAGUS.

DR. BURNEY, of St. Louis. I have had a somewhat similar case to that reported. A tailor swallowed an ordinary silver case-knife, which passed into the stomach. I saw him one hour after the accident and performed gastrotomy. The incision was made in the linea alba. The knife was found lying transversely with the handle towards the pylorus. A short incision was made, the knife removed and the opening in the stomach closed with a double row of sutures. I think that in such cases the continued suture is to be condemned.

Next came the discussion on DR. DENNIS' paper on

AMPUTATION OF THE HIP.

DR. DONALD MACLAIN, of Detroit. An important practical point is with reference to the method of restraining hæmorrhage. The mortality in olden times was largely due to the defective measures of controlling bleeding. The method described by Dr. Dennis seems open to the objection that the elastic band might slip, when the operation was delayed. I have amputated the hip a number of times and have had the utmost satisfaction from the use of Lister's abdominal compressor. I believe that this is superior to any other method for controlling hæmorrhage in this region. If the compressor is not at hand the fists of an assistant will answer the purpose, the compression being made on the umbilicus.

DR. WEEKS, of Portland, Maine. I have employed an elastic compressor consisting of the ordinary black rubber bandage, doubled so as to make four strands ten feet in length. This is passed between the thighs, brought between the tuberosity of the ischium and the rectum, and up in front over the femoral artery. An ordinary roller bandage is placed over the artery. The ends are brought over in front and held by an assistant. This also controls hæmorrhage from the gluteal vessels.

DR. GUNN, of Missouri. I understood the author to state that he did not know of a case of sarcoma of femur which was alive one year after operation; I assisted at an operation on a case of sarcoma on the lower third of the thigh. Eighteen months later the patient was living and healthy.

DR. REYHER, of St. Petersburg. I think that in emaciated subjects it would not be advisable to make such sudden compression as is caused by Lister's compressor. I have used the rubber tourniquet but without special satisfaction. I have performed another operation. I make an excision in the head of the bone; I then place a stick through the wound and another in front, securing them together by rubber bands. The same thing is done with the posterior portion. The flaps can then be cut without hæmorrhage. In three operations I have had no disagreeable results from this measure.

DR. W. BOONE, of Shanghai, China. No one has alluded to the method proposed by Dr. Furnell Jordan. Where there is sufficient tissue free from disease, this seems to present many advantages. This operation is performed by making a circular cut through the muscles low down, making a flap and then turning back the flap. The bone is next divided. An excis-

ion of the head is next made. In this way you cut the vessels low down and the control of bleeding is absolute.

Dr. Palmer, of Jonesville, Wis. I have used a method similar to that of Dr. Reyher. Instead of sticks, I have passed pins of sharpened steel wire through the limb in front and behind the bone and then securing them to other pieces in front of and behind the limb.

Dr. Chavasse, of Birmingham, England. In amputating for malignant disease, the less tissue left the better. Therefore the operation of Mr. Furnell Jordan is not a good one for this particular disease. The best method is that known as Brodie's operation by anterior and posterior skin flap. In children the best plan for controlling hæmorrhage is by digital compressor. This is also applicable in thin subjects. I have also used Dary's rectal staff with satisfaction.

IODOL,

by Dr. Assaky, of Bucharest, Roumania. The conclusions of this paper were as follows:

(1) Wounds unite under iodol by first intention. This union, however, being the result of various and complex conditions attending operation, it is not possible to attribute to iodol alone the absence of suppuration and inflammatory conditions. In wounds which gape and suppurate iodol is an excellent antiseptic. It rapidly retards suppuration, renders it inodorous, reduces the frequency of dressing, and hastens considerably cicatrization. In ulcerating or gangrenous wounds iodol aids to resist the destructive process and changes the wound, after a variable time, to a healthy granulating condition. This action of l'iodol extends itself to hard chancres. In case of soft chancres the result is variable. Sometimes it transforms them into a simple wound with brief delay; at others it is insufficient for this purpose, and it becomes necessary to employ in addition, locally, antiseptic lotions. The same is true with reference to open venereal bubos of the groin. The powdered iodol has this advantage over iodoform, that it is free from odor and is not toxic in its effects.

(2) Doses of iodol of from 0.40 centigrammes to 2. grammes daily, produce no functional trouble, even if continued a long time. These doses give marvelous results in tertiary syphilis, and in scrofulous affections. In the secondary stage of syphilis, taken internally, it rapidly destroys the syphilitic manifestations. Iodol seems to aid the general nutrition and increase strength and flesh. It is indicated in all cases of specific malnutrition.

Iodol is an antipyretic. In acute infectious diseases, such as erysipelas, etc., it causes a rapid fall of temperature.

PARACENTESIS OF THE ARTICULATION IN THE EARLY STAGES OF DISEASES OF THE HIP-JOINT,

by Mr. Edmund Owen, F.R.C.S., of London, England.

It is generally admitted that the sero-synovial effusion, associated with early acute disease of the hip-joint has an influence on the stiffening and faulty position of the limb. In these cases examination will usually show a deep-seated fulness below the middle of Poupart's ligament, which advances the femoral vessels towards the surface. There is also swelling behind and between the great trochanter and the tuberosity of the ischium. An illustrative case was given. A boy, nine years of age, was admitted to St. Mary's Hospital, London, on account of extreme pain in the right hip and knee. The limb was semi-flexed, and the foot slightly everted. The attempt to bring the limb down, caused tilting of the pelvis and arching of the loins. There were all the signs usually regarded as indicating the first stage of hip-joint disease. There was slight fulness in the positions indicated. The pain had come on suddenly two weeks previous in a child apparently healthy. Chloroform was administered, but the leg remained stiff. A trocar and canula were passed through the back of the capsule, and a teaspoonful of sero-purulent fluid, containing flakes of lymph was withdrawn. The femur could then be extended and the joint was loosened. An extension apparatus was applied, and the patient was perfectly at rest. On the fourth day he was free from pain. The convalescence ran a perfect course, terminating in recovery in two weeks.

It may be said that this was not a case of hip-joint disease, but one of simple synovitis. This was admitted, but if the capsule had not been tapped, there might have developed suppurative arthritis. If this is admitted, the author claimed that potential hip-joint disease might be cured by paracentesis.

We should always be on the lookout for this condition. Where we cannot be absolutely certain that there is distension, we should give the patient the benefit of the doubt, and perform exploratory puncture. This, if done with clean instruments and ordinary care, is devoid of risk.

DISCUSSION.

Dr. L. H. Sayre, of New York. I believe that the case which he relates, if allowed to go on, would probably have ended in rupture of the capsule and perhaps destruction of the head of the bone. In the early stage of the disease when the limb is flexed, everted and abducted, as a result of over-distension of the capsular ligament, if the fluid is not absorbed by rest and counter-irritation, it is proper to puncture the joint, thus treating the hip-joint the same as any other joint.

Dr. G. W. Boone, of Shanghai, China. I think that it is well to report what we can in this connection. Two years ago my attention was called to the injection of joints with glycerine and iodoform. This I used in a number of joints. I used it in two cases where there were evidences of the first stage of hip-joint disease. In one case the symptoms disappeared, while in the other, the case ran the ordinary course of a case of hip-joint disease.

Dr. Lange, of New York. In the case reported, the child probably had tubercular disease near the hip-joint which ruptured into the joint causing effusion. In such cases the painful symptoms can be relieved by tapping the joint. To regard this as an effective treatment for hip-joint disease which must be regarded in children as essentially a tubercular affection, seems hardly proper. This case is not concluded, and we do not know what the final result will be.

Dr. Owen. This was not a case of tubercular process in the joint. The attack began two weeks before admission, was an acute effusion, and recovered within two weeks after operation. Tuberculosis does not run this course.

Next in order was the discussion on the paper of DR. GARMANY,

ON TREPHINING FOR EPILEPSY,

read on Wednesday.

DR. BURNEY, of St. Louis. I have had one case of epilepsy and mania, for which I trephined. There was a clear history of injury to the head. The skull had been trephined without good effect. I also performed trephining. When the bone was removed, the dura mater came up into the opening. This I incised and at once there was an enormous flow of cerebro-spinal fluid. I introduced four catgut sutures to close the opening in the dura mater. The patient recovered, but there was no immediate improvement, although since then there has been some lessening of the number of the seizures.

(To be continued.)

AMERICAN GYNÆCOLOGICAL SOCIETY.

TWELFTH ANNUAL MEETING.

THE Twelfth Annual Meeting of the American Gynæcological Society was held in the hall of the Academy of Medicine, New York, September 13, 14 and 15, 1887.

FIRST DAY— TUESDAY, SEPTEMBER 13TH.

MORNING SESSION.

The Society was called to order by the President, DR. A. J. C. SKENE, of Brooklyn. After the calling of the roll the

ADDRESS OF WELCOME.

was delivered by DR. FORDYCE BARKER, of New York.

MR. PRESIDENT, Fellows of the American Gynæcological Society, and friends who honor us with their presence: The pleasing duty has been assigned me to welcome you in behalf of the Resident Fellows of New York and Brooklyn, and in behalf of the Academy of Medicine.

Our Society is organized for mutual edification and not for mutual admiration. I therefore resist the temptation to congratulate ourselves on the good work that we have accomplished in these eleven years. It is conceded that in no department of medicine has there been a more rapid growth. It may be asserted that both talent and genius have been developed and consecrated to these departments. I remember to have met this terse distinction between talent and genius: "To do easily what others do with difficulty, that is talent, to do what talent cannot do, that is genius."

Talent and genius are both original endowments and are, therefore, not qualities of which to boast, but I feel warranted in referring to the success of our Society in one of its aspects.

Our discussions have not been wanting in sharp criticism, but not in a single instance has there been in our discussions anything bearing the semblance of personal rancour. Neither has the time of our meetings been wasted in listening to profitless and wearisome discussions of personal claim to priority.

Many of you, our distinguished foreign guests, are known to many of us personally. All of you are well known to all of us by the good work that you have done. We give you a warm welcome with the anticipation that the interests of this meeting will be largely enhanced by your participation in its work.

In accepting the honorable duty assigned to me, I have felt it incumbent on me to bear two things in mind: First, that the duty is specific, simply to welcome the Society and its guests; second, that this welcome should be as short as possible, so that no time be lost for our scientific work.

It therefore only remains for me to congratulate you, Mr. President, that you have the honor to preside over such a body, and to congratulate the Society that it has you as its presiding officer.

A STUDY OF THE CAUSES AND TREATMENT OF UTERINE DISPLACEMENTS,

by DR. THOMAS ADDIS EMMET, of New York.

The mere version cannot be regarded as the disease in those cases in which it is found. It is but a symptom. The degree of prolapse or elevation of the uterus below or above a certain line causes the symptoms. If we examine a woman suffering with prolapse, the pulsation of some branch of the cervical artery can be readily detected. When the uterus is raised to the health line a sense of relief is felt, and if it be held there for a few minutes the pulsation ceases. If, however, the uterus is raised beyond this point distress is again experienced. Anteversion is certainly not an abnormal position. Retroversion to a marked degree is frequently detected through accident where it has not given rise to the least inconvenience. Many years ago the author had shown that the most reliable means of relieving the symptoms due to anteversion, where the displacement was not due to inflammation, was a retroversion pessary with a long posterior curve. This acts by raising the neck and the body, more or less.

With reference to the causes, the speaker remarked that he would not take time to speak of the more common causes with which all were familiar, but he wished to refer to the influence of pelvic inflammation in inducing displacement. The only fixed point is in front of the neck of the bladder, where the subpubic ligament binds down the urethra. Any traction on this point leads to irritation and a desire to empty the bladder. This often results from inflammatory adhesions. The uterus may be retroflexed or anteflexed, but the traction will be upon the urethra. Prolapse is the more usual consequence of pelvic inflammation, resulting from the increased weight due to the obstructed circulation. The degree of displacement is usually in proportion to the extent of the cellulitis. The effect of peritonitis involving Douglas's cul-de-sac is to raise the uterus, while versions always result from pelvic cellulitis. In cases where the inflammation is confined to the utero-sacral ligaments there will be anteversion.

In a case of backward displacement, the uterus is usually comparatively free so that the displacement can be corrected with the finger. If the organ be held in what is supposed to be its correct position, pulsation will soon be detected in some of the neighboring vessels. If a pessary be introduced under these circumstances, it will soon be necessary to remove it. In extreme anteversion the displacement cannot be corrected by means of any instrument without making traction upon the utero-sacral ligaments, and if this is done inflammation will be the result. In the treatment

of cases of displacement the result of inflammation, the general practitioner should not resort to pessaries, but should, if treatment is necessary, apply iodine, use cotton and glycerine pads, and order hot water injections.

The pelvic circulation presents certain pecularities. In no other part of the body can so much blood be received in cases of disease. The veins are without valves and their course must be tortuous in order to overcome the force of gravity. The author had observed that if the uterus be drawn down to the floor of the pelvis and held there, the cervix and vaginal tissue become congested as the result of obstruction of the venous circulation. If, however, the traction be increased until complete procidentia is induced, the tissues become blanched as a result of the narrowing of the arteries from the traction. The relations between the pelvic tissue and the circulation were then referred to.

The whole skill in the use of the pessary consists in constructing it of such size and shape that while it relieves the prolapse it will just dispose of the overstretching. The relief is not dependent entirely upon relief of the version. Its effect is indirect, consisting in the relief of congestion. The speaker had also used cotton saturated with glycerine to lift the uterus. The quantity used was never more than sufficient to correct the prolapse. If a large quantity is employed, it is liable to cause irritation. The profitable range for the use of pessaries is not extensive. If not employed with great caution and judgment, the effects to the patient may be very serious. He believed that nothing can take the place of pessaries when properly fitted and used in the proper class of cases. He thought that their field of usefulness was more limited than is generally supposed. The displacement should not be corrected on its own account until the history of the case has been ascertained. No attempt should be made to correct the displacement so long as any evidences of recent inflammation are present. In tracing the histories of a large number of women, no instance of permanent cure has been found from the use of pessaries, in cases where there was reason to believe that previous inflammation had complicated the case.

DISCUSSION.

Dr. Graily Hewitt, of London. The subject of displacements of the uterus has occupied my attention for a considerable period. The conclusions advanced are such as in a general way I should agree to. There seems to be a difference between American and English women with reference to the frequency of cellulitis. I have not found this complication in a large number of cases of uterine displacements. In regard to the causes of uterine displacement, it seems to me that Dr. Emmet has limited himself almost entirely to the effects of inflammation. I think that the question of the general causes of displacement are very important. The speaker has attributed the sufferings of the patient to pressure by exudation. He has not alluded to a point which I consider important, and that is, that the flexure in the uterus interferes with the circulation and causes pressure upon the nerves. To this cause I would attribute a large part of the pain. Simple straightening of the uterus relieves the discomfort. In cases of acute flexion when the sound has been used in the treatment, I have observed that when the instrument reaches the internal os, this part is found excessively sensitive. By completing the introduction and straightening the uterus, the tenderness disappears within twenty-four hours and does not return.

There is something more to be said with reference to the use of pessaries when there is pelvic cellulitis. I agree that pessaries should not be used if there is acute congestion present. I think that there may be cases in which there is contraction and hardness associated with displacement in which pessaries may be very valuable in leading to absorption of the exudation. The pessary must of course be fitted carefully and properly applied.

Prof. A. R. Simpson, of Edinburgh. The last speaker has suggested that there must be a difference between the females of America and of England with reference to pelvic cellulitis. I think, however, that the difference is more with the mind of the individual who examines these cases. The same woman going to several different observers might get a different opinion from each. One, looking at the general aspects of the case, might consider it a neurosis, while another, looking at the local conditions would regard it as a case of uterine displacement.

I agree with Dr. Hewitt that the author has not taken a very large view of uterine displacements. He seemed to confine himself to the results of inflammation and to displacements occurring in women who have had children. We also have displacements in women who have been married two or three years and have not conceived. In some of these cases we have inflammation, and this is not to be overlooked. Even after we have done all that we could in the way of relieving the inflammation, it is necessary to put the uterus in proper position to fit it for impregnation.

Dr. G. Bantock, of London. I am unable to agree with the author with reference to the frequency of pelvic inflammation. I think that perhaps the best explanation is the one given by the last speaker. I believe that experience is teaching us that pelvic inflammation is less common than we have generally supposed. Many of the cases regarded as pelvic cellulitis have been instances where the inflammation was confined to the Fallopian tube or the peritoneum lining Douglas's cul-de-sac, and especially the peritoneum covering the Fallopian tube.

I have not seen the utility of paying so much attention to the causes of displacement. In a case of a broken arm we do not inquire particularly as to the exact manner in which the injury was received, so in cases of displacement of the uterus, I do not trouble myself with regard to the cause of the trouble. The patient comes to be relieved and I proceed to relieve her as best I can. My experience is, that in the majority of cases perfect and permanent relief can be afforded by the proper use of the pessary. The proper adjustment of the instrument is the whole secret. After confinement where there is retroversion, I recommend, where the uterus is not adherent, replacement by the sound and a pessary properly applied. Where there is much tenderness it is not desirable to at once apply the pessary, but the congestion should first be relieved. Where adhesions have formed the use of the pessary must be set aside altogether.

I recall one case which I saw with Dr. J. Marion Sims, where there was well-marked retroversion. There was also supposed to be disease of the appen-

dages, and the patient was sent to me for operation. While it was possible to replace the uterus with the sound, it at once resumed its former position, when the sound was withdrawn. The abdomen was opened and it was found that there were adhesions between the fundus of the uterus and the lower portion of the pelvis. These adhesions were divided, and the result was a perfect cure.

DR. T. A. EMMET, of New York. The causes of displacement of the uterus are many, and most of them are well known. My object was to call particular attention to one class of cases which are overlooked, and which are complicated with inflammatory troubles, which will not be discovered unless an examination by the rectum is made. This is the reason there is such a diversity of opinion.

There is no one who uses pessaries more than I do, and in the majority of cases pessaries should be used and nothing else can be used, but there is a class of cases in which the use of pessaries is improper.

As regards the frequency of pelvic inflammation, I believe that it is less common abroad than in America. Our young women go into society earlier, and they contract pelvic inflammation as a result of imprudence in dress. I have found the effects of pelvic inflammation more commonly among the unmarried than among the married. The sterility which follows may perhaps be attributed to displacement of the fimbriated extremity of the Fallopian tube, and not so much to occlusion of the tube.

CYSTOCOLPOCELE COMPLICATING LABOR AND PREGNANCY,

by DR. SAMUEL C. BUSEY, of Washington.

This term is applied to the prolapse of the bladder into the vaginal passage. The prolapse may be partial or complete. It may occur anteriorly or laterally. It is well known that distension of the bladder frequently complicates labor, but the subject of cystocolpocele has not received much attention. It is a rare accident, and, when present, often overlooked. The author had been able to find six reported cases of cystocolpocele complicating pregnancy. Where the distended bladder can be detected externally, there is no difficulty, but where the prolapse is into the vagina, many of the cases are doubtless regarded as cases of threatened abortion. The speaker reported the following case occurring in his practice:

November 24, 1886, he was called to see a woman in the ninth month of pregnancy. It was thought that labor had commenced. The pains occurred at short intervals. The finger in the vagina at once came in contact with a distended pouch. The os could not be felt, and no presenting part could be discovered. It was learned that no urine had been passed since the previous day. With the fingers of one hand in the vagina, while percussion was made above the pubes, distinct pulsation was observed. It was then concluded that the case was one of distended bladder, prolapsed into the vagina. The patient was then assisted by the nurse to the commode, and passed a large quantity of urine. The tumor at once disappeared, the cervix could be reached, and labor had not begun. In this case, vesical tenesmus was not present.

The histories of the other five recorded cases were given in abstract.

Cases of cystocolpocele complicating labor, although rare, are more numerous than cases of the same condition complicating pregnancy. The author had found thirty-seven such cases recorded. Mistakes in diagnosis have often been made, and on several occasions, the bladder has been punctured, under the impression that it was the amniotic sac.

The cause of this affection is not known. It occurs in multiparous women who have to work hard. In most of the cases there has been presentation of the head. The condition is usually accompanied with pains somewhat like those of labor, but unaccompanied with any progress towards expulsion of the fœtus. In some cases there is complete retention of urine, with frequent desire to empty the bladder. More frequently, there is a scanty discharge of urine, with vesical tenesmus. If the prolapse is partial and the organ empty, a firm, hard mass, marked with rigor, will be found. If the bladder is completely prolapsed, or partially or incompletely filled with urine, there is an absence of internal serum above the pubes, and a tumor will be felt in the vagina, completely closing the vaginal canal. The finger can be swept over the lateral and anterior portions of the tumor, but not in front. Where the prolapse is anterior, labor cannot be completed until the urine is removed. The only certain sign of this affection is the discharge of urine through the urethra, and the subsidence of the swelling.

DISCUSSION.

DR. WILLIAM GOODELL, of Philadelphia. I have met with two cases of this condition: one a few days before labor, and the other during labor. In the first case, the nurse sent for me on account of peculiar symptoms. I found a body as large as the child's head, and as hard. There was severe vesical tenesmus. I could not pass the finger behind the tumor, and there was no evidence of an os uteri. Further examination showed the swelling to be due to the distended bladder. A catheter was readily introduced, and relieved the swelling. There was no return of the trouble. The other example of this condition occurred in a case of antero-posterior contraction of the pelvis. The pain was very great, but the cause of the difficulty was soon recognized. I found it impossible to introduce either the soft or the metallic catheter. I put on the forceps, and raised the head so that the catheter could be passed in. The labor was then completed with the forceps.

This condition is more apt to occur when the conjugate diameter is narrowed. In this case, the head plays on the brim of the pelvis before it enters, and any sudden contraction of the abdominal walls may cause a portion of the bladder to come down between the head and the pubes. After fixation of the head occurs, its onward movement tends to carry the bladder with it.

Adjourned.

(To be continued.)

— By the will of the late B. F. Caldwell, the Concord (N. H.) Hospital will receive $5,000.

— A Western lay contemporary suggests an important therapeutico-commercial truth in the following colloquy: "To what do you attribute the curative properties of your springs?" asked a visitor at a health resort. — "Well," answered the proprietor thoughtfully, "I guess the advertising I've done has had something to do with it."

THE BOSTON

Medical and Surgical Journal.

THURSDAY, SEPTEMBER 22, 1887.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: *$5.00 per year, in advance, postage paid, for the United States and Canada; $6.00 per year for all foreign countries belonging to the Postal Union.*

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

ANTIFEBRINE AS AN ANALGESIC.

In a lecture recently delivered in Cochin Hospital,[1] Dujardin-Beaumetz set forth a property of antifebrine — more correctly called acetanilide — which it possesses in common with antifebrine; namely, that of antagonizing pain. He calls attention to the fact that such of the new antithermics as cause a fall of temperature by a direct and special action on the thermic centres of the spinal cord would, *à priori*, seem likely to be beneficial in affections of the nervous system that are unattended with fever, and their theoretical prevision has been substantiated by recent clinical experimentation. Thus salicylic acid has become an analgesic, and has been employed with success in neuralgias, and even in tabes dorsalis, and antipyrine has proved itself to be an anodyne of the first order; and, according to Professor Germain Sée, likely to supersede morphia as a remedy for subcutaneous injections in painful affections. Professor Sée injects seven-and-one-half grains, dissolved in a hypodermic syringeful of water, and repeats the injection three or four times in the twenty-four hours. He finds antipyrine thus administered to be unirritating, and no less efficacious in subduing the pain than morphia.[2]

Acetanilide was discovered by Gerhardt, in 1835, by acting on a phenylamine with chloride of acetyl. It was, however, only a year ago that it began to come into use as a medicine, when, in consequence of its manifest antithermic property, it was named antifebrine by Drs. Cohn and Hepp, of Strasbourg. Shortly afterward, Lépine, of Lyons, experimenting with acetanilide in apyretic maladies, found out its analgesic properties; and Dujardin-Beaumetz, taking a hint from the results obtained by Lépine, tried it, with signal success, in nervous disorders in Cochin Hospital.

This clinical experimenter has employed acetanilide in combatting three orders of phenomena: the element of pain in general, then the special pains of locomotor ataxia, and lastly, epilepsy.

Under the first head, he remarks that acetanilide has proved itself inferior to aconitia in the treatment of facial neuralgia; but when the cephalic pains are linked to nerve alterations, as, for instance, in certain cases of neuritis of the nerves of the orbit, acetanilide has been found to be superior to any other remedy. He cites the case of a patient who had suffered long and intensely from cephalic and periorbital pains, which, for months, had resisted aconite, bromide, and iodide of potassium, and which completely disappeared under twenty-grain doses of acetanilide. He has also obtained good results from acetanilide in the pains of acute rheumatism, myalgia, and various pains of neuralgia.

These results have been confirmed by Demieville, of Lausanne, who has shown that relief begins to be experienced very soon — often in a quarter-of-an-hour, though generally not till one or two hours, after the administration of the acetanilide. Demieville also ascribes to the new remedy marked somniferous qualities. In sciatica and in intercostal neuralgia, its analgesic effects have been most marked.[3]

In the lightning pains of locomotor ataxia, Dujardin-Beaumetz has obtained great benefit from acetanilide, complete relief following full doses; and like success in the treatment of these formidable pains by the same remedy has been claimed by Dr. Signé, of Montpelier. Beaumetz, however, records the fact that the relief obtained is not lasting, that the anodyne effect of the remedy in tabes dorsalis, though administered every day, is soon exhausted, lasting only about a fortnight. Fischer, moreover, has reported ten cases of ataxia in which the *douleurs fulgurantes* were treated by acetanilide. Nine were markedly benefited.

In several cases of epilepsy in which the Cochin Hospital chief made trials of acetanilide, amelioration was experienced, the convulsive crisis being lessened. In one case, that of a child twelve years of age, the improvement was most striking. Bromide of potassium had been given without any decisive results, and was finally suspended, on account of bromism. Acetanilide was then given in doses of seven-and-one-half grains, three times a day. Three months had elapsed since this treatment was instituted, and during that time the child has been quite free from epileptic attacks. Other clinical authorities, however, have tried acetanilide in epilepsy without success (Faure, Jolly, Salm).

Acetanilide is insoluble in water, but soluble in wine, in which it may be conveniently administered. As an analgesic, it should be given in doses of seven or eight grains, two, three, or four times a day.

The tests of the purity of this drug are given by Yvon as follows: "It should be odorless; it should be perfectly white. Heated on a platinum-foil, it should give a colorless liquid. Thus heated, it should be completely volatilized, and should leave no residue. Treated with hypobromite of soda, it should not give an orange-yellow precipitate."

JOHN HUNTER AS A SYPHILOGRAPHER.

AT the time when John Hunter's work on Venereal appeared, he was at the height of his fame, and the book upon which he was known to have spent so much labor, attracted universal attention. Appearing in 1786 it was followed the next year by a French and a German translation. In 1788, the second English edition was published, and 1791 the first American. Other editions in English, French and German followed at various intervals up to 1859, with prefaces and notes by distinguished syphilographers, until it can be said that no work on Venereal before or since Hunter has ever met so distinguished a reception.

A new era began with Hunter and he is regarded even yet, as one of the most noted syphilographers in medical history.

One error he is universally known to have taught, that of the identity of gonorrhœa and syphilis, but it is a little startling to see the era inaugurated by Hunter characterized as one of deterioration and most fearful mistakes. Such is the characterization of his teaching as expressed in an article in the *Vierteljahrschrift fur Dermatologie und Syphilis*, by Proksch, of Vienna. The description is intended to apply only to his work on syphilis and not at all to his labors in other fields. Hunter's treatise on Venereal is the result of his own observation, and is written with but little acquaintance with the then existing literature, and one of the interesting points in the article to which we refer, is found in the reference to errors of Hunter's which he might have avoided by a knowledge of previous writers.

In Hunter's time the distinction between gonorrhœa and syphilis was already recognized, but in 1767 Hunter undertook his well-known but unfortunate experiment of inoculating pus from a urethral discharge upon healthy skin, a chancre, followed by constitutional syphilis, was the result, and Hunter accordingly taught that the contagium of gonorrhœa and syphilis were identical. This doctrine, in spite of many attacks based upon many negative experiments was held by the majority of physicians for a half century, or until it was overthrown by Ricord.

Previous to Hunter's publication there was much debate as to the possibility of inoculating the disease by kisses, the use of drinking-cups and instruments, and by the hands of physicians and midwifes, and it was held that the secretions of secondary affections and the blood must carry the contagium. Hunter attempted to throw light upon the subject by experiment; and he inoculated various syphilitic individuals with the secretions of their own sores with negative results, while from inoculation from chancres on syphilitics he claimed to have produced chancres, and he drew the inference that the secretions of secondary affections are not inoculable even upon the healthy, and consequently he doubted or denied all the cases in which infection takes place through the blood or normal and pathological secretions. The transmission of syphilis to offspring, Hunter seems also to have doubted, though he describes clearly a most interesting family history in the chapter on "Diseases resembling the Lues Venerea."

In regard to syphilitic disease of interior organs, Hunter said, "we have not seen the brain affected, nor the heart, stomach, liver, kidneys, nor other viscera; although such cases are described by authors," an expression of opinion which served to banish all reference to internal syphilis from the text-books and from men's minds, for a half-century, until the advance in pathological anatomy again brought it to light.

Syphilitic ophthalmias were also denied by Hunter, although recognized by older syphilographers, because the so-called syphilitic symptoms in the eye were more painful than other syphilitic manifestations, and because the ophthalmic lesions never resulted in suppuration.

Even the honor of first describing the induration of the initial lesion is not rightfully ascribed to Hunter. In 1779, John Andree described the indurated chancre in language quite as striking as Hunter's and the induration is plainly, though not so fully, mentioned by previous writers from Fallopius down.

A GRATEFUL PATIENT'S ESTIMATE OF THE PROFESSION.

WE have all been taught from our early years that it would be greatly to our advantage to see ourselves as others see us, but the advantage was supposed to consist in the better view of our own faults which might enable us to free ourselves from follies which are very prominent to the eyes of our neighbors. Whether equal advantage arises from a similar outside view of our virtues may be doubtful, but it is very certainly a pleasure to feel that we are seen as we would *like* to be seen, especially if the one who sees us and tells what he sees, has in other matters shown himself to be a person of sound judgment. Robert Louis Stevenson, the clever writer who is known to us as the author of the "New Arabian Nights," "Dr. Jekyll and Mr. Hyde," "Kidnapped," and lately as the graceful critic and essayist in "Men and Books," as well as a charming and original maker of verses, has undertaken in the preface to his latest volume "Underwoods," to answer the question, who are "the men and classes of men who, either as a rule or under some more or less exceptional circumstances, may be said to stand above the common herd." Stevenson enumerates the soldier, the sailor, the shepherd not infrequently; the artist rarely; more rarely still the clergyman; the physician, almost as a rule.

"He," the writer claims, "is the flower (such as it is) of our civilization — the possessor of generosity such as is possible to those who practice an art, never to those who drive a trade; of discretion tested by a hundred secrets; tact tried in a thousand embarrassments, and what are more important, Heraclean cheerfulness and courage. So it is that he brings air and

cheer into the sick room, and often enough, though not so often as he wishes, brings healing."

Mr. Stevenson, it will be remembered, has not led the life of a recluse, but has been an extensive traveller, is apparently well acquainted with men and things, and has "enjoyed" much of many physicians within a range from San Francisco to Montpelier, and Bournemouth to Davos Platz. He considers himself under special obligation to eleven physicians, but states they are only a few out of many who have brought him "comfort and help."

It might be thought that we of the guild, on reading this high praise, might be in danger of making "broad our phalacteries" to an alarming extent, and thanking God we are not as other men are. We do not, however, suppose that Mr. Stevenson meant to imply that every practitioner of the healing art was a flower such as it is of civilization. Perhaps he may not be justified in drawing his conclusions from even his unusually large experience.

If any man feels himself in danger of being puffed up by such praise, he need only look up the articles published, about six years ago, in England, to feel that some, at least, there are who see another side to the profession. But surely, the profession has had a training which must make its members, to a certain extent, indifferent alike to praise and blame, for, indeed, no class of men are praised and blamed so indiscriminately.

There are, we are glad to know, in the ranks of the profession not a few who deserve all the praise contained in the sentences quoted; if others are conscious that Mr. Stevenson's estimate, as applied to them, is exaggerated, it may prove, at least, a stimulus to cultivate the qualities with the possession of which his active imagination has too gratefully endowed them.

SMALL PARKS AS BREATHING SPACES.

By a wise act of the New York Legislature at its last session, provision was made for establishing new small parks, from time to time, in various parts of the city below One Hundred and Fifty-Fifth Street, and last week, at the Mayor's office, there was held a meeting of the Committee of the Board of Street Opening, to whom the matter had been referred, for the purpose of discussing suitable sites for the parks in the tenement-house districts, where they are most needed, as well as in the upper wards, which are not as yet closely built up. Dr. John T. Nagle, of the Health Department, presented a report showing the number of residents to the acre, in the different wards of the city, which range from two in the 24th Ward, to 433 in the 10th. In eight of the down-town Wards, the population is over two hundred to the acre, and these were the ones which he believed to be most urgently in need of the small parks. According to the provisions of the new law, not more than $1,000,000 can be expended for the purpose in any one year, and it is, therefore, estimated that about one park a year can be laid out.

MEDICAL NOTES.

— Despatches from Rome, under date of September 19th, say that the cholera afflicting the inhabitants of Messina is of the most violent character, death frequently ensuing an hour after the attack. The mortality is not confined to the lower classes. There is great misery among the people. The grave-diggers refuse to pursue their calling until compelled to by the troops. The epidemic has appeared in the prisons.

— A correspondent writes to *Science* that in the Texas grazing region, from which has sprung, within the last two decades, the entire stock of range cattle of the western states and territories, the beef tapeworm is a most common occurrence. In fact, he asserts that at least every fifth person is afflicted. The cause of this is that on open ranges the eggs of tapeworm are most easily and widely distributed, and hence the cattle more frequently become infested with cysts. Stall fed cattle, on the other hand, where the water is usually less subject to contamination, and the food cleaner, are only seldom infected, and hence tape-worm was not so prevalent in regions where the latter were used.

In the last few years, however, the shipment of range-cattle, by means of refrigerator cars, has become the chief beef supply of the East, and the danger and frequency of tape-worm greatly increased. Of course, no one should stop the use of well-cooked meat on this account, but rare and half-cooked meats can easily be avoided.

NEW YORK.

— At a meeting of the Board of Health held August 31st, ten of the summer corps of visiting physicians were transferred to the vaccinating corps.

— At a meeting of the Board of Health, held September 7th, Dr. W. de Forest Gay was relieved of the duties of Registrar of Vital Statistics. He remains Sanitary Superintendent (a position which he has filled in a most satisfactory manner for many years), at a salary of $4,800 per annum. Dr. Roger S. Tracy, Chief Sanitary Inspector, was appointed Registrar of Vital Statistics, his salary being advanced from $2,600 to $3,000, and Major Willard Bullard was made Chief Sanitary Inspector. Dr. Taylor, Chief of the Bureau of Contagious Diseases, was directed to prepare and present a plan for the instruction of medical and sanitary inspectors, having in view the more satisfactory control of all preventable diseases. On and after January 1, 1888, there is to be a first grade of medical inspectors, who, for the first three years, shall receive a salary of $1,200 per annum. They may then be promoted, for merit and satisfactory service, to a second grade, at $1,500 a year for two years; then to a third grade, at $1,800 a year for three years; and finally, to a fourth grade, at $2,000 a year.

— On September 14th, Archbishop Corrigan, of the Roman Catholic Church, laid the corner-stone of the new St. Joseph's Hospital for Incurables with appro-

priate ceremonies. This institution will occupy a block in the annexed district beyond the Harlem, on the eastern side of the city. The site is a fine one, directly opposite the new St. Mary's Park, and the main building, which fronts on 143d Street, is to be two hundred and forty by one hundred feet. Back of this and fronting on 144th Street, will be the residence of the Sisters of the Poor of St. Francis, who are to have charge of the hospital, and between the two buildings, and connecting them, will be a chapel. The cost of the whole is estimated at $250,000, and there will be accommodation for two hundred and fifty incurable patients.

— The College of Physicians and Surgeons, which is about to occupy its magnificent new buildings opposite the Roosevelt Hospital, announces that, after the session of 1887–88, preliminary examinations will be required in the cases of all applicants for matriculation who profess to enter for the degree of M.D., except from those who have been graduated at recognized colleges or can present certificates to the effect that they are proficient in the branches included in the preliminary examination prescribed by the College. The examinations are to be in writing, and will be held semi-annually.

— It is said that Dr. Charles E. Simmons, who is at present one of the Commissioners of Charities and Correction, has presented a bill of $143,000 to the trustees of the estate of the late Samuel J. Tilden, for services rendered during the life of the deceased. Dr. Simmons was on terms of intimacy with Mr. Tilden, and visited him almost every day for about eight years. If the amount named is correct, its large size is probably due to the fact that during a very considerable portion of this time his patient resided at his country-seat on the Hudson, above Yonkers.

— During the recent annual meeting of the American Gynæcological Society, which was held at the Hall of the New York Academy of Medicine, there were present a number of distinguished foreigners who had been in attendance at the meeting of the International Medical Congress, in Washington, and among these were Drs. Graily Hewitt and George Granville Bantock, of London, A. R. Simon, of Edinburgh, G. Apostoli and A. Doléris, of Paris, August Martin, of Berlin, and A. Cowles, of Geneva. On the evening of September 13th, Dr. P. F. Mundé entertained these gentlemen, with a number of American guests, at a dinner at the Union League Club, and on the 15th, the annual dinner of the Society was held at Delmonico's; while on the 14th, Dr. Fordyce Barker gave a large reception at his house to the American Gynæcological Society, its distinguished foreign guests, the Obstetrical Society of New York, and the members of the Obstetric Section of the New York Academy of Medicine.

— The fourth annual meeting of the New York State Medical Association, will be held at the Hotel Brunswick, September 27, 28 and 29.

Miscellany.

A NEW MEANS OF DETECTING ALCOHOLIC AND SIMULATED STATES OF COMA.

DR. VON WEDEKIND, writing in the *Medical Record*, claims a sure method of detecting malingerous hysterics and alcoholic patients, which he has practised successfully in the Ambulance Service of the Chambers Street Hospital, New York. He says that by simply pressing on the supraorbital notches with a steadily increasing force, one may, with a certainty of success, detect a malingerer; bring an unconscious alcoholic to his senses, and thus differentiate on the spot between alcoholic and other comas; cause cessation of hysterical convulsions, and in many instances quiet violent alcoholic delirium. The best way of applying this test is: When the patient is in the recumbent position, the physician, standing at the head of the cot, or kneeling when the patient is on the ground, fixes the tips of the thumbs over the supraorbital notches, as above described, never minding the occasional yell or struggle, press steadily, gradually increasing the force, and in half a minute or a minute the result is accomplished.

The success of this method he illustrates from the fact that of the 213 alcoholic patients to which the ambulance was called, 137 were comatose, the police and friends being utterly unable to arouse them, and this treatment brought 128 of the 137 to consciousness. Of the cases where no result was obtained, 5 were, besides alcoholism, suffering from cerebral concussion, two fracture of the base of the skull, one uræmic coma, and one from syncope from valvular heart trouble.

In the 18 cases of hysteria there was absolute success; no one case failed to respond, and the same with malingerers. Nine of twenty-eight cases of delirium tremens quieted down and spoke rationally; in the remainder there were varying degrees of success; some becoming more quiet, while in others but little change was noticed.

OBITUARY.—CHARLES ELIOT WARE, M.D.

A shining light was extinguished in the death of Dr. Charles Eliot Ware, which took place suddenly, on Saturday, September 3d. It is surely appropriate that a surviving friend and contemporary should bear testimony to his worth and his excellence, and should try to hold up to the younger members of the profession, who have not known him in his days of strength and activity, a model of the faithful, honest, skilful practitioner of medicine. The path of a medical practitioner has its special trials and temptations. The patients and attendants can not always judge of the skill and honesty of his work. The fear of God and an enlightened conscience are greatly needed for faithful work. With all the helps and restraints of medical colleges, associations and societies, greed, ambition and selfishness do claim their victims. He, who in a long life as a practitioner of medicine, has always been honest, honorable and unselfish, commands our admiration.

Dr. Ware's chief inheritance was a good name. His father, for many years the Professor of Divinity in Harvard University, known and respected of all men, two brothers, ministers of the gospel, highly esteemed in the community where they labored, a brother in great repute a as practitioner of medicine and a valuable and honored professor of the theory and practice of physic in Harvard University were among his forbears. He took up their mantle and maintained his integrity during a life of

more than three score and ten years. We can safely point to his character as worthy of admiration and imitation.

He had a good education, graduating at Harvard College in the class of 1834 and from the Harvard Medical School in 1837. He neglected no opportunities of self-improvement. Fidelity to duty was the aim of his life. His numerous patients recognized in him a counsellor to whom their interests and welfare were the paramount object. He trained his intellect, he stored his mind with knowledge for their benefit. He had naturally a sound judgment, a dignified deportment, unfailing courtesy. He was emphatically a just man. His brethren of the profession felt they were always safe in his hands. Of no one did he ever take advantage. He never sought honor or public office. He accepted and faithfully discharged all duties assigned to him. He was a Visiting Physician at the Massachusetts General Hospital from 1857 to 1867, when he resigned and was appointed upon the Consulting Staff. He was a trustee, a member of the executive committee and vice-president of the Board of the Boston Lying-in-Hospital, and this useful institution owed much to the active and intelligent interest which he always manifested in its welfare.

He served the Massachusetts Medical Society for six years as Secretary. For three years he was the Secretary of the Boston Society for Medical Improvement. He sought emolument only in the faithful performance of work.

The duties of a son, brother, husband and father were discharged with love and fidelity. He was always considerate of the poor and needy. His professional skill was always at their disposal, and he was foremost in all charitable work.

Such men are an honor and credit to the profession. Dr. Ware's example is a legacy. He has gone where brilliant talents, great riches and honors are of avail only as they have been used for others. His friends may fondly anticipate for him that verdict which we all must covet, "Well, done, good and faithful servant."

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 10, 1887.

Deaths reported 1,821: under five years of age 804; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 481, consumption 222, lung diseases 120, diarrhœal diseases 259, diphtheria and croup 96, typhoid fever 51, malarial fevers 27, scarlet fever 16, whooping-cough 14, cerebro-spinal meningitis eight, erysipelas six, puerperal fever three, small-pox (New York) one. From malarial fevers, New Orleans 12, New York nine, Charleston three, Baltimore two, Nashville one. From scarlet fever, New York 10, Baltimore and Cambridge two each, Boston and Pittsburgh one each. From whooping-cough, Boston five, New York four, Baltimore, Pittsburgh, Milwaukee, Cambridge and Lawrence one each. From cerebro-spinal meningitis, New York three, Washington, Fall River, Lynn, Somerville and Brockton one each. From erysipelas, Baltimore, New York, Boston, Pittsburgh and Worcester one each. From puerperal fever, Washington two, New Bedford one.
